OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION

1898-1899

GENERAL OFFICERS

PRESIDENT—JOSEPH M. MATHEWS,	Louisville, Ky.
FIRST VICE-PRESIDENT—W. W. KEEN,	Philadelphia, Pa.
SECOND VICE-PRESIDENT—J. W. GRAHAM,	Denver, Colo.
THIRD VICE-PRESIDENT—H. A. WEST,	Galveston, Texas.
FOURTH VICE-PRESIDENT—J. E. MINNEY,	Topska, Kansas.
TREASURER—HENRY P. NEWMAN,	100 Washington St., Chicago, Ill.
SECRETARY—WILLIAM B. ATKINSON,	Philadelphia, Pa.
ASSISTANT SECRETARY—E. W. WOODRUFF,	Columbus, Ohio.
LIBRARIAN—GEORGE W. WEBSTER,	Chicago, Ill.
CHAIRMAN COMMITTEE OF ARRANGEMENTS,	Starling Loving, Columbus, Ohio.

BOARD OF TRUSTEES—E. E. Montgomery, Pennsylvania, 1899; H. L. E. Johnson, District of Columbia (unexpired term), 1899; C. A. L. Reed, Ohio, 1899; Joseph Eastman, Indiana, 1900; J. T. Priestley, Iowa, 1900; Truman W. Miller, Illinois, 1900; Alonzo Garselon, Maine (President), 1901; T. J. Happel, Tennessee, 1901; I. N. Love, Missouri, 1901.

JUDICIAL COUNCIL—Term expires 1901: S. Bailey, Iowa; D. R. Brower, Illinois; N. S. Davis, Illinois; H. D. Didama, New York; D. Mason, Washington; F. T. Rogers, Rhode Island; Milo B. Ward, Missouri. Term expires 1900: D. W. Crouse, Iowa; R. C. Moore, Nebraska; T. D. Crothers, Connecticut; G. B. Gillespie, Tennessee; W. T. Bishop, Pennsylvania; C. H. Hughes, Missouri; Ida J. Heiberger, District of Columbia. Term expires 1899: G. W. Stoner, U. S. M.-H. Service; C. W. Foster, Maine; J. McFadden Gaston, Georgia; W. S. Jones, New Jersey (unexpired term); H. Brown, Kentucky; X. C. Scott, Ohio.

SECTION OFFICERS

Officers of Sections, 1898-99.

Practice of Medicine—Frank Billings, Chicago, Chairman; Carroll E. Edson, Denver, Secretary.

Surgery and Anatomy—W. J. Mayo, Rochester, Minn., Chairman; M. L. Harris, Chicago, Secretary.

Obstetrics and Diseases of Women—A. H. Cordier, Kansas City, Mo., Chairman; W. D. Haggard, Nashville, Tenn., Secretary.

Materia Medica, Pharmacy and Therapeutics—Thomas H. Stucky, Louisville, Ky., Chairman; Leon L. Solomon, Louisville, Ky., Secretary.

Ophthalmology—Casey A. Wood, Chicago, Chairman; Chas. H. Williams, Boston, Secretary.

Laryngology and Otology—Emil Mayer, New York City, Chairman; Christian R. Holmes, Cincinnati, Secretary.

Diseases of Children—Henry E. Tuley, Louisville, Ky., Chairman; L. D. Boogher, St. Louis, Secretary.

Physiology and Dietetics—J. Weir, Jr., Owensboro, Ky., Chairman; Lee Kahn, Leadville, Colo., Secretary.

Neurology and Medical Jurisprudence—Frederick Peterson, New York, Chairman; Hugh T. Patrick, Chicago, Secretary.

Outaneous Medicine and Surgery—W. T. Corlett, Cleveland, Chairman; J. M. Blaine, Denver, Secretary.

State Medicine—Arthur R. Reynolds, Chicago, Chairman; W. P. Munn, Denver, Secretary.

Stomatology—George V. I. Brown, Milwaukee, Chairman; Eugene S. Talbot, Chicago, Secretary.

General Business Committee, 1898-99.

Practice of Medicine—Wm. E. Quine, Chicago; J. H. Musser, Philadelphia; S. A. Fisk, Denver.

Surgery and Anatomy—C. A. Wheaton, St. Paul; Reginald Sayre, New York City; W. L. Rodman, Louisville, Ky.

Obstetrics and Diseases of Women—J. Tabor Johnson, Washington; Milo B. Ward, Topeka; Joseph Price, Philadelphia.

Materia Medica, Pharm. and Therapeutics—J. V. Shoemaker, Philadelphia; Frank Woodbury, Philadelphia; Warren B. Hill, Milwaukee.

Ophthalmology—Lucien Howe, Buffalo; G. E. de Schweinitz, Philadelphia; Harold Gifford, Omaha.

Laryngology and Otology—G. V. Woolen, Indianapolis; Wm. E. Casselberry, Chicago; B. Alex. Randall, Philadelphia.

Diseases of Children—A. C. Cotton, Chicago; (Vacancy); J. P. Crozer Griffith, Philadelphia.

Physiology and Dietetics—H. Bert Ellis, Los Angeles; A. P. Clarke, Cambridge, Mass.; Randell Hunt, Shreveport, La.

Neurology and Medical Jurisprudence—T. D. Crothers, Hartford, Conn.; W. J. Herdman, Ann Arbor, Mich.; Chas. H. Hughes, St. Louis.

Cutaneous Medicine and Surgery—L. Duncan Bulkley, New York City; A. Ravogli, Cincinnati; A. W. Brayton, Indianapolis.

State Medicine—Chas. H. Shepard, Brooklyn; Elmer Lee, New York City; (Vacancy).

Stomatology—A. E. Baldwin, Chicago; M. H. Fletcher, Cincinnati; R. R. Andrews, Cambridge, Mass.

Executive Council—W. J. Herdman, Ann Arbor, Mich., Chairman; Warren B. Hill, Milwaukee, Vice-Chairman; C. A. Wheaton, St. Paul; J. H. Musser, Philadelphia; L. Duncan Bulkley, New York, Secretary.

ORIGINAL ARTICLES.

DISEASES OF THE LACHRYMAL PASSAGES—THEIR CAUSES AND MANAGEMENT.

Read before the Monroe County Medical Society.

BY LEARTUS CONNOR, A.M., M.D.

DETROIT, MICH.

The lachrymal passages are insignificant in size, but their diseases tax to its utmost the resources of surgical art. There are few constitutional conditions with which they may not be associated, while the technique of their diagnosis and operation calls for sound judgment and the finest manipulative skill. Failure to recognize anatomic deformities or the cause of the lachrymal disease renders futile the highest operative technique; while the most profound appreciation of causation or pathology can not cure without such technique.

The study of a million cases, treated in public clinics, shows that diseases of the lachrymal passages form about 2.5 per cent. of all eye cases. In private practice the proportion is larger, as well-to-do people seek surgical relief sooner. My records of 7909 cases show that 493, or about one in eighteen, had some disease of the lachrymal passages.

The causes of diseases of the lachrymal passages are general and local, functional and organic. Notable among general diseases is syphilis. By lesions of the eyelids it may evert the puncta, causing epiphora; by lesions of the conjunctiva directly, or indirectly through the iris, it may evert the puncta or obstruct the canaliculi or extend to the sac and cause a dacrocystitis. More frequently syphilis induces dacrocystitis by attacking the nose, the duct or adjacent bones. This may take the form of periostitis, endostitis or subperiosteal gummas. A mucous patch on the wall of the nose over the site of the mouth of the duct may obstruct the flow of tears. Purulent dacrocystitis indicates, generally, disease of the periosteum or caries of the bone about the duct. The bony wall of the duct may be destroyed by caries or necrosis, the sequestra of the latter calling for removal by operation. Gummy growths occur in the wall of the duct and sac, obliterating the passage very rapidly and leading to suppuration. Hyperplastic processes of the bones themselves have been known to encroach upon and obstruct the lachrymal passages. Gout, rheumatic gout or the state antedating the acute attacks is responsible for many cases of lachrymal diseases attacking the bony, fibrous or mucous tissues here as in other portions of the body. Tubercular and scrofulous disease not infrequently invades some portion of the lachrymal passages, as also do the infectious diseases, scarlet fever, diphtheria, measles, typhoid fever smallpox. All these and other constitutional diseases may approach the lachrymal pass-

ages by first inducing a conjunctivitis or disease of the nose, and so attack the passages from either end or both. But a purely local conjunctivitis or blepharitis may cause obstruction, obliteration or malposition of puncta; narrowing of the lachrymal canals, inflammation of the lachrymal sac or engorgement of the lining membrane of the duct. This obstruction may be temporary as in congestion, or permanent as in stricture; it may be attended with an overflow of tears alone or tears thickened by mucus or pus, or both.

In like manner local disease of the nose may cause engorgement of the mucous membrane of the duct and its surrounding plexus of blood vessels; a thickening of the connective tissue, forming strictures; an ulcer may close the duct; a tumor may occlude it; hypertrophies or atrophies of the nares may obstruct to a greater or less degree the current of tears to the nose. Finally, defects of refraction may cause, directly or indirectly, disease of the lachrymal passages. That these defects do cause conjunctivitis and blepharitis is a fact long since established. It is also established that conjunctivitis and blepharitis may cause diseases of the puncta, canalicula and sac, therefore the possibility of eyestrain causing lachrymal disease must be granted. Besides, careful observation will show that the strained efforts to secure better correction of optical defects does occasionally turn the puncta from its normal position and so cause an overflow of tears or their undue retention within the tear passages and so favors their decomposition and renders them irritating. It disturbs the muscular rhythm by which the tears are forced through the canaliculi, sac and duct. In short, eye strain does in some cases derange the normal current of tears to the nose and incite disease of the lachrymal passages.

It is not true that every case of eye strain induces lachrymal disease, nor is it true that it induces blepharitis and conjunctivitis: it is only affirmed that in some cases it has such an effect. Clinically, for many years, I have observed that all cases of disease of the lachrymal passages had some defect of refraction, the correction of which clearly promoted treatment and in the milder forms was curative alone.

These several causes may induce disease of the lachrymal passages: By occluding the puncta in whole or part or by displacing it from its position against the eyeball in the lachrymal lake; by swelling the mucous membrane; by weakening or otherwise disturbing the action of the orbicularis; by diminishing the elasticity of the sac; by engorgement of the vascular plexus about the duct; by occlusion of the lower end or any portion of the duct; by the formation of strictures; by ulceration of the mucous membrane, or by disease of the bony walls.

All lachrymal obstructions afford the microbic hordes an opportunity to render the tears so irritating as to extend the existing inflammation and intensify its character. As this process continues mucus and

then pus or a mixture of tears, mucus and pus results; the sac becomes distended and finally passes into a phlegmon of the connective tissues about the sac; the pent-up accumulation finally breaks through the skin and discharges upon the cheek. Watching the progress of these events in a patient, we find at first a slight cold, with red and tearful eyes. While the redness and constant epiphora soon disappear, slight irritation by dust or wind causes the tears to again overflow, first at long intervals, then at shorter and shorter ones. A little swelling is observed at the inner angle of the eye, pressure upon which is followed by discharge of mucus and tears into the lachrymal lake or the nose. The intervals between the refilling of the sac gradually diminish until it is almost constantly full. Now, after some undue exposure, a swelling is noticed about the sac, red, tender, growing with much rapidity, very painful, often mistaken for erysipelas and finally after great suffering the phlegmon breaks and discharges its mucopurulent contents upon the cheek. Unless the natural openings of the sac become free with the reduction of the swelling, the discharges continue upon the cheek causing distressing excoriation, the tears and mucus gather between the eyelids, obstruct vision and finally flow over the lids to the cheek, keeping the eye red and the subjacent skin inflamed. If by some accident an abrasion of the corneal epithelium occurs the malignant germs enter and take possession, causing corneal ulcers, abscesses or even iritis. Neglect of these, equal to that of the lachrymal passages, is followed by great crippling of vision if not entire loss.

It will aid an intelligent management of these cases to bear in mind a few points relative to the structure and functions of the lachrymal passages. They begin with the puncta of the upper and lower lids, continue inward to the sac, thence through the duct to the nose. The puncta are hardly larger than the point of a pin and held firmly against the eyeball, within the lachrymal lake. The canaliculi starting from the puncta pass perpendicularly to the edge of the lid for a little, then turn and pass horizontally inward to the sac, which they generally enter by a common canal. They are lined with pavement epithelium on basement membrane, surrounded by connective tissue and muscular fibers, offshoots from the orbicularis. The sac is lined with columnar epithelium, as is the duct, resting on basement membrane, and this upon an elastic wall, all filling the lachrymal fossa and partially covered by the internal ligament, which alternately compresses and relaxes the sac. The mucous membrane of the duct is like that of the sac, but surrounded by a rich plexus of blood vessels and the whole encased within bony walls and opening into the floor of the nose, behind the lower turbinated bone. Its membrane is thrown into folds at its mouth and at junction with the sac, which may easily be injured by careless probing. The canaliculi are narrowed at the junction of the horizontal portion with the sac and the perpendicular. As the tears emerge from the conjunctival and lachrymal glands they are swept along the eyeball by the closure of the lids toward the lachrymal lake, being set back from the inner commissure by the caruncle. The contractions of the orbicularis now force the secretion through the canaliculi into the sac; the latter by suction caused by its elastic rebound from previous compression aids in the movement. As the eyelids open the sac is compressed by the internal ligament and the tears pressed into the

duct, whence they pass to the floor of the nose. Doubtless this is aided by the weight of the fluid, by capillary attraction and possibly by syphonage. In any given case the problem presented is to secure a permeable lachrymal passage with smooth lining membrane, puncta pressed against the eyeball in the lachrymal lake and normal muscular action and elasticity of the sac. The forces propelling the tears through the lachrymal passages are muscular action and sac elasticity. In the management of a case of lachrymal obstruction:

1. All eye strain should be removed, from either refractive error or loss of muscular equilibrium.

2. In all stages of every case much aid can be secured by the systematic local application of hot water; because of its convenience a tumbler is employed. Filled with hot water it is so placed that the entire eye is immersed within its contents. Varying with the effects called for, this application may be made for from ten to fifteen minutes every hour, or less frequently. The water must be as hot as the skin can bear without scalding. Thus used, hot water contracts the vessels with flabby walls, securing a more rapid current of blood therein, allays irritation, is a powerful aseptic and antiseptic and promotes repair of the diseased tissues, even within the sac and duct. To the water may be added any aseptic drug, as boric acid, and the conjunctiva washed therein by winking the eyelid.

3. In the earlier stages of lachrymal disease, the regular and systematic helping nature to empty the sac, using an aseptic solution to refill it, is attended with excellent results. It promotes a more nearly normal current of fluid through the passages, aids in restoring the lost elasticity of the sac, improves the tone of the orbicularis, reduces the engorgement of the mucous membrane and cleanses it of debris. Gould suggests the following method: The patient is placed in a reclining position, with the head thrown back and toward the side opposite the eye to be treated, in such a manner as to form a basin in the corner of the affected eye. This basin is filled with a solution of boric acid or other aseptic solution, and the forefinger alternately presses and relaxes the sac, practically pumping the fluid in the basin through the lachrymal passages. This should be done three or more times daily, for from five to ten minutes, according to the indications in each case. This is expected only to reach functional and inflammatory derangements, though if practicable it will benefit organic lesions.

4. For purposes of diagnosis and treatment, syringes with tips small enough to readily enter the puncta, are of value. There are many forms of these, but Anel's is most commonly employed. When the canaliculus is so opened as to admit of passing a fair-sized probe through the duct, de Wecker's canula probes may be used. Being introduced as is the probe, the style is withdrawn and a syringe attached to the upper end and the fluid passed through the passages. A syphon or fountain syringe may be attached and medicated or hot water forced through the passages to any desired amount, an advantage over the small syringes that compel removal with the discharge of the contents of one barrel, and a reintroduction, which is more or less painful.

5. In all cases the puncta should be examined with minutest care. If an eyelash be found within, it is readily removed with forceps; if a concretion or other foreign body be engaged in the perpendicular portion

of the canaliculus, it is removed by dilating and manipulation, or this failing, by slitting the puncta. If the puncta be permanently everted, the perpendicular portion of the canaliculus must be divided on the inside. A fine pointed scissors readily does this little operation. Should this fail a bit of conjunctiva is removed from the base of the vertical cut, and if this fails the canaliculus must be divided. The end sought by these operations is to secure apposition of the outer end of the canaliculus to the eyeball, within the lachrymal lake. If the puncta is partially occluded it must be dilated; if it is closed it must be opened, best by the canaliculus knife when the edge of the lid is placed upon tension by being pulled outward.

6. If there be reason to suspect stricture of the canaliculus, its location is decided by passing a lachrymal probe through the canaliculus to the sac. A small probe, No. 2 Williams' or Bowman's, is taken in the right hand between the thumb and finger and the patient's head steadied against the operator's chest. The forefinger of the left hand draws the edge of the lower lid outward and downward so as to make the canaliculus straight and tense. The point of the probe is inserted vertically in the puncta and when fairly entered, turned horizontally in the line with the canaliculus. With gentle, firm movement it is moved along till it meets the hard resistance of the inner wall of the sac. If there be resistance, as shown by wrinkling of the skin about the canaliculus the probe is withdrawn a little and then moved forward in a slightly different direction, a maneuver which may need repeating many times before a tight stricture be safely passed. Care must be exercised not to push the probe through the canal wall at the side, rather than through the stricture. In this manner, by using one probe after another, the stricture may be definitely located and dilated.

If after the sac is entered it be desired to explore the duct, the handle of the probe is raised while its point is kept against the inner wall of the sac, until it has reached a vertical position, the direction of the probe being toward the wrinkle at the ala nasi, when it is moved gently but firmly downward till the floor of the nose is reached. The same care must be exercised in passing obstructions as in the canaliculus. Here also we may use probes of varied sizes and shapes, as the case may call for, in diagnosis or treatment. In no operation is gentleness and constant care more necessary than in the probing of the lachrymal passages. One must have such self-control as to wait, if failure attends the first effort, until swelling has been reduced or the exact twist of the passage ascertained. It is easy to make false passages at the entrance to the sac, at the opening of the duct, and farther down to denude the bone. It is easy to break through the lachrymal bone at the floor of the orbit and otherwise do such damage as shall make the further management of the case extremely difficult and disappointing.

Many strictures may be managed by dilatation with probes of various sizes, in addition to the treatment already described, but most of those coming to the surgeon are of such long standing as to require a division of a portion or all of one or both canaliculi. This operation is done as follows: A probe-pointed little knife as Weber's or Agnew's is taken in the hand as was the probe, the patient and operator occupying the same positions. The lid is placed upon stretch in the same manner and made to enter the

puncta as was the probe. The edge of the knife is turned slightly inward so that the incision shall lie in contact with the eyeball in the lachrymal lake, and then pushed inward, as was the probe, to the hard inner wall of the sac. The knife is now lifted to a position more or less near the vertical position, and as is called for by the amount of the canaliculus, desired to be divided, it is then drawn outward cutting through the thin wall of the passage. If it is desired to divide the stricture at the neck of the sac or within the duct, the knife is raised to a vertical position, as was the probe, and guided into the duct and pushed through the stricture. If freer division is called for the blade is withdrawn a little, turned partially about and again moved through the obstruction.

The probes employed for dilating lachrymal strictures are numerous. The first were introduced by Bowman, and they still retain their hold upon the profession; for general uses they have never been excelled. They range in size from 1 to 8, are made of silver sufficiently stiff to retain any given form, and malleable enough to admit of being molded into the form of the canal under treatment. Williams introduced bulb-pointed, flexible-shank probes, adapted to feeling their way about obstructions whose exact location is undetermined, with pleasing facility. Their sizes have the same range as those of Bowman. Other probes, as those of Theobald, are of sizes reaching to that of the bony canal, or as Weber's conical, the end of the cone being at the point, so that many sized probes are united in one. While I have used every variety, the ones best suited to ordinary cases are the Bowman and Williams probes.

To keep open dilated strictures, styles are used. They are left in place constantly, except at the time of cleansing or altering the size. They are introduced as probes and of such length that the tip may be at the floor of the nares and the head just outside the sac, with such enlargement as admits of easy grasping for removal. Silver and lead are favorite materials, as these metals are little acted upon by the secretions. It has seemed to me that their use was much like the treatment of urethral stricture by the constant wearing of sounds. In place of these styles, if unable to keep the patient under observation, I teach him or some of his family to pass the probe.

Cases of mucocoele or dacryo-cystitis are treated by opening the lachrymal passages by operation, keeping them dilated by probes, promoting their nutritive activities by means already described, and treating the constitutional diseases with which they are associated. If it be impossible, in case of lachrymal phlegmon, to enter the sac through the canaliculi, it is best to open it between them. Even cases of lachrymal fistula recover by means already described. It is granted that cases of excessive destruction of the mucous membrane lining the canals furnish little hope of securing a permeable smooth passage, with an elastic sac. Yet one is often agreeably surprised by the excellent results of most unpromising cases.

If permanent occlusion of the duct occurs, from unremovable conditions, and the suffering of the patient demands, the sac may be destroyed, or the lachrymal gland removed, or both. It has never been my fortune to meet a case calling for such operations. In no case should the constitutional condition of the patient be overlooked. In syphilis specific treatment cures many cases without operations. In cases of

gout or gouty rheumatism, local treatment without constitutional, is unsatisfactory. In cases of infectious disease, the general treatment will not be forgotten.

In general it may be said that if treated in the early stages disorders of the lachrymal apparatus result satisfactorily; if later, the chances of satisfactory results rapidly diminish, and at the last some are failures in spite of the best directed medical and surgical skill. Illustrative of certain types of lachrymal diseases are the following brief abstracts of cases:

N. H. aged 6 years, on recovering from scarlet fever was attacked with inflammation of the left lachrymal sac and surrounding cellular tissue. The tears constantly discharged themselves on the cheek. The pain was intense. The swelling when first seen, was as large as a small egg and exquisitely tender, red and hot. The mother said that the tears began to overflow soon after the onset of the fever and had rapidly grown worse. Under chloroform the sac was opened, through the lower canaliculus and the pus evacuated, the cavity cleansed with a warm solution of boric acid, and poultices applied when the hot water could not be used. The relief to the child was prompt and the treatment soothing. In about four weeks the swelling had entirely disappeared and the lachrymal passages pervious.

General K., aged 68 years, sought relief from an annoying epiphora of the right eye of long standing. Mucus and pus escaped with the tears, causing an inflammation of the cheek, blurred vision, etc. He was an old sufferer from rheumatic gout. Strictures were found at the junction of the canaliculus with the sac, at the entrance of the duct into the sac and at its lower extremity, and much bare bone between. There was considerable bare bone at the inner and upper portion of the external meatus of the right ear, showing that the constitutional disease was not limited to the lachrymal duct. The canaliculi, both upper and lower, were divided to the sac with the strictures therein, and at the same time the strictures of the duct. The passages were kept open with suitable probes, and as aseptic as possible by measures described, and the local and general nutrition promoted by exercise, diet and mineral baths. The recovery was perfect in about eight months, the bare bone having become entirely covered with a smooth membrane.

Mrs. F. P., aged 25 years, had suffered from red weeping eyes many years, rendered much worse by exposure to wind, cold or any irritant. Examination showed half a diopter of hyperopic astigmatism with the rule in each eye. This was corrected, the patient directed to soak her eyes in hot water for ten minutes, each eye three times daily, and to irrigate the lachrymal passages with a saturated solution of boric acid after each soaking. In two months the patient reported complete recovery.

Mr. J. B., aged 35 years, desired relief from a watering and stickiness of the right eye. The lachrymal sac was found moderately dilated, so that pressure upon it caused a flow of its contents from the puncta and into the nares. Examination revealed a stricture at the junction of the canaliculi and duct with the sac. These were divided and treated by dilatation, with perfect recovery in four months, the sac having fully regained its elasticity, an essential condition of a good result, because the mechanism of the passage of tears through the passages depends very largely upon that elasticity.

Mr. S., aged 28 years, a molder, was attacked by lachrymal obstruction in the tertiary stage of syphilis. The progress from simple epiphora to mucocoele and dacryocystitis was very rapid. After reducing the acute inflammation, by opening and aseptic cleansing, the strictures at the junction of common canaliculus with the sac and at the opening of the duct were divided. Bare bone was found throughout most of the duct. He was placed upon large and cumulative doses of iodid of potassium, and the passages kept as aseptic as possible and fully dilated by probes. Recovery was complete in about a year, the passages becoming lined with a smooth membrane. At first visit the necrosed turbinated bones were removed.

CONCLUSIONS.

1. Among the predisposing causes of diseases of the lachrymal passages are such defects of structure as flattening of the bony canal or other irregularities, and defects of refraction.

2. Syphilis, gout, phthisis, scrofula, or any of the infectious diseases may cause lachrymal disorder.

3. Among the local causes are conjunctivitis at the upper end of the lachrymal passage, and nasal disease at the other end, the morbid process in either instance spreading to the canal nearest.

4. The management of any case will never overlook the bearings of any constitutional disease; especially does antispasmodic treatment furnish gratifying results.

5. All defects of the refraction should be corrected under a mydriatic and muscular equilibrium assured.

6. Diseases of the conjunctiva and eyelids, as well as all nasal disease, should be removed.

7. The treatment of the lachrymal passages with aseptic solutions through small syringes, or the forced washing by Gould's method, and the systematic external use of hot water, contribute to better results in all forms of these disorders.

8. The puncta should be rendered pervious, and their position against the eyeball assured by local treatment if possible or, this failing, by operation, so that the ends of the canaliculi may be fully within the lachrymal lake.

9. Strictures should be located by probes and either dilated or divided by instruments, the extent of the operations depending upon the nature of each special case.

10. Cases treated early in the disease give uniformly good results; those attended with large destruction of tissue are less hopeful, the epiphora often remaining in spite of treatment, but they are protected against the danger of future attacks of dacryocystitis.

THE MORBID ANATOMIC EVIDENCES OF THE LYMPHATIC CONSTITUTION IN IDIOPATHIC EPILEPSY.

Remarks accompanying a demonstration of specimens before the Chicago Pathological Society at its annual meeting, May 9, 1898.

BY A. P. OHLMACHER, M.D.,

Director of the Pathological Laboratory of the Ohio Hospital for Epileptics.

GALLIPOLIS, OHIO.

This opportunity of demonstrating before the Chicago Pathological Society a series of specimens illustrating some recent studies upon the morbid anatomy of epilepsy is one for which I am grateful, and it is a pleasure to thank my friend, Dr. Hektoen, and his associate, Dr. Le Count, for their kindness in according me the privilege of bringing to your notice a subject in which I am intensely interested, and one which, since it involves the intelligent examination of gross pathologic objects, seems especially adapted for presentation before a society composed of experienced pathologists. Not to overstep the bounds of propriety incident to this particular meeting I shall endeavor to condense as much as possible what seems necessary to say in explanation of the objects submitted to your inspection.

In the course of an investigation into the pathology of epilepsy, carried on since last July at the Ohio Hospital for Epileptics, a series of uniform and hitherto undescribed conditions have been found at autopsy in certain cases of epilepsy, and it is to these particular conditions that your attention is respectfully invited.

It is scarcely necessary to remind you that no constant gross or microscopic lesion has been discovered in epilepsy, especially in what we might style "pure"

epilepsy, or "primary" epilepsy, or idiopathic *grand mal*. This may, in part at least, be due to the fact that attention has too exclusively been concentrated upon the central nervous system to the neglect of the body as a whole, and that too much weight has been laid upon changes in the brain which are doubtless of a secondary character, due to the action of some extrinsic cause. This poverty as regards somatic details will be fully appreciated by anyone who searches the literature of epilepsy with the desire of obtaining postmortem records in which the data has been determined with that exactness and fulness demanded by modern pathologic research.

It was precisely this condition of affairs that led us, on commencing our work, to look with especial care to the gross and microscopic pathology of the cases which came to autopsy, in the hope that the data carefully gathered and reliably recorded would ultimately furnish statistics from which conclusions could be drawn; and that eventually there might be established what has always been lacking as a foundation for the study of epilepsy, and what is fundamental for the rational study of any disease, viz.: a morbid anatomy.

Eighteen cases have been examined postmortem since this work was inaugurated, and in eight of these cases some distinctive features were met, which, from their comparative constancy and singularity were regarded as more than accidental occurrences. These eighteen cases represented various types of epilepsy and the insanities accompanied by epileptoid phenomena. The findings at autopsy naturally varied widely in these cases, as would be expected from their clinical diversity. The details with reference to the first six of them were recorded in the *Bulletin* issued by the hospital last January; and in another publication, to be ready in a short time, the full account of the eighteen cases will be given.

So far as the clinical side is concerned it is important to note that these eight cases include all of the examples of typical idiopathic *grand mal* which have thus far been examined at postmortem. The patients were all young adults, varying in age from 17 to 35 years. All of them, except one, suffered with epilepsy from childhood. Four of them had periodic epileptic mania. One man died from maniacal exhaustion; one committed suicide; two women and one man were found dead in bed after having retired in apparent good health, which is to say (and this should be emphasized), that out of the eight cases there were three instances of sudden death, in at least two of which no lesion to account for the abrupt ending could be found.

The gross pathologic anomalies in these eight cases, which are illustrated by the specimens to be submitted for your examination, may be summarized as follows: A persistent, enlarged, and apparently active thymus body; a pronounced hyperplasia of the intestinal and splenic lymph-follicles; a more or less marked hypertrophy of the lymphatic glands, and of the lymph-adenoid follicles of the tongue, larynx, trachea, esophagus, tonsils, and even of the stomach; a narrowing of the arteries; an abundant development of fat; an enlargement of the thyroid; and certain osseous changes indicative of old rickets. Not all of these abnormalities were present in a single case, though the persistent thymus, with one or more features added, was constant. With the specimens before you it will not be necessary to enter into

minutiae of description since you will readily recognize the thymic body, the enlarged follicles, narrow arteries, etc.

Taken collectively, these morbid anatomic conditions make a picture of what the German pathologists style the "lymphatic constitution." The evidences of the lymphatic constitution have been noted for a number of years in connection with several diseases, but never, so far as I can determine, have they been described in connection with epilepsy.

There are two morbid conditions, accompanied by a more or less perfect picture of the lymphatic constitution, which seem especially important in relation to what we have found in our epileptics. One of them is laryngismus stridulus, or more exactly, what the Germans style "thymic asthma," which is well known clinically, and which is often responsible for very sudden death in the infants affected. The other condition is sudden death in apparently healthy adults with no assignable lesion, and in whom only the persistent thymus, with other evidences of the lymphatic constitution, is found at autopsy. It is impossible to discuss these extremely interesting morbid states in the time at our disposal, and it must be sufficient simply to emphasize the fact that the morbid anatomy of the lymphatic constitution is peculiar, not only to these conditions, but, apparently also, to at least certain cases of idiopathic epilepsy. Of this morphologic analogy there can be little doubt, and in the report upon four of our cases in the January *Bulletin*, arguments were advanced for defining a clinical as well as anatomic analogy between thymic asthma, thymic sudden death, and epilepsy.

What the significance of the lymphatic constitution is, in its relation to thymic sudden death, is not at all clear, although numerous hypotheses have been called into account; and this is precisely the case in relation to our own work where this peculiar anatomic picture has been shown to occur in certain epileptics. Without resorting to pure speculation the present state of our knowledge in relation to the lymphatic constitution prohibits an explanation, and since speculation has played too exclusive a part in the attempts to account for that mysterious malady, epilepsy, we propose to refrain from indulging in this very tempting pastime.

With this naturally very much condensed introduction, which will, I trust, make them more intelligible, I beg to submit the specimens which illustrate the persistent and hyperplastic thymus; the intestinal and splenic lymphatic hyperplasia; the narrow arteries; the hypertrophied lymphatic glands; and the excessive development of fat; which were obtained from three of the eight epileptics, all of whom presented the typical picture of the lymphatic constitution at autopsy.

CEREBRAL SYPHILIS AND SOME OF ITS MENTAL ASPECTS.

BY ARTHUR E. MINK, M.D.

Professor Mental and Nervous Diseases, College of Physicians and Surgeons; Neurologist to the Baptist and Woman's Hospitals; Clinical Lecturer on Neurology, City Hospital; Formerly Physician to the New York City and King's County Insane Asylums.
ST. LOUIS, MO.

The complicated manifestations of brain syphilis, when given their proper interpretation, are of the utmost value to the student of scientific medicine.

Nature, working in her own laboratory with its marvelously delicate adjustments and contrivances, is continually performing a series of brain experiments which infinitely surpass those performed by man with his crude and clumsy technique.

The syphilitic neoplasms are of such an ephemeral character, coming and going, here today and there tomorrow; that they frequently give us the opportunity to study in one and the same case all of the kaleidoscopic and complicating phenomena of focal and diffuse, destroying or discharging lesions, present simultaneously or successively. It is just this lack of order, this protean appearance and disappearance, which is characteristic of the phenomena of cerebral syphilis. So we may meet with cases which up to a certain time have shown signs of focal involvement only, and then develop suddenly symptoms of syphilitic melancholia, hallucinatory insanity or dementia; or, on the other hand, we may meet with cases which have shown for a long time only the mental phases of cerebral syphilis, suddenly develop hemiplegia and ataxic aphasia in an apoplectiform attack. Again, we meet with cases in which the history and examination show the presence of focal and diffuse, destroying and discharging lesions side by side and complicating each other. The lesions of cerebral syphilis are either osteal, meningeal or cerebral, but only those tissues of mesoblastic origin are involved *per se* by the luetic process.

When the bones of the cranium are affected, we either find a simple sclerotic or gummatous periostitis. There may be a gummatous osteomyelitis and the inflammatory atrophy of Virchow (caries sicca). When the dura is involved we have to deal with a pachymeningitis externa or interna combined with a gummatous meningitis. The gummata occupy by preference the processes of the dura. More usually gummata are found in the subarachnoidal space. They are whitish-red, grayish or grayish-red masses. They are diffused or circumscribed, but are never sharply demarcated from the neighboring brain substance, which is usually in a state of white or red softening. They undergo caseation from the center to the periphery, slowly becoming changed into yellowish masses. On the convexity of the brain they cause adherence of the meninges to each other and to the softened brain tissue. At the base adhesions are rarer, and usually instead of gummata we find a gelatinous grayish exudate, similar in extent and appearance to that of a tuberculous meningitis. If the syphilomatous mass is absorbed there is left a thickened cicatrix. It is rarely or never that we find gummata in the brain substance proper without any anatomic connection with the meninges. We often meet with diffuse encephalitis, more particularly of the cerebral cortex.

One of the most important lesions of cerebral syphilis, one that does most damage to the circulation and nutrition of the brain, is that form of endarteritis first described by Huebner, which involves largely the endothelium of the interna along with an exudate of leucocytes from the vasa nutritia, which together form a new growth, ultimately obliterating the lumen of the vessel affected. Those of the base are usually involved and especially the arteries of the fossa of Sylvius and corpus callosum. Softenings are naturally produced in the areas supplied by these obliterated arteries. This more particularly is found in the nucleus lenticularis and caudatus. The

cranial nerves are also often affected through the shrinking of basilar exudates.

It is claimed by some authors that no definite lesions can be found postmortem in some cases of cerebral syphilis. There may be some truth in this and we think it is especially so of those cases of brain disturbance which sometimes occur in the earlier stages of the disease. The writer recalls two cases of syphilitic coma occurring before and during the first cutaneous manifestations, which can only be explained by assuming the presence of cerebral intoxication, due to intensity of infection. Broadly speaking, we can say that there is a certain relation between the location of the lesions and the resultant symptoms produced by them. So can a gummatous lepto- or pachy-meningitis produce symptoms of cortical irritation, especially of epilepsy, often accompanied by mental disturbance. Occlusion of the larger arteries often produces the characteristic symptoms of syphilitic coma or symptoms due to thrombotic ischemia of cortical or subcortical areas, such as brachial or crural monoplegia, facial palsy, amnesic or ataxic aphasia, etc.

A gummatous basilar meningitis gives us an interesting mixture of cranial nerve palsies, accompanied by hemiplegia. Alternating hemiplegia of the ocular type accompanied by ptosis is very common in basilar syphilis. In fact, ocular palsies are so common in cerebral syphilis that Ricord used to say: "*Un paralytic oculaire c'est en quelque sorte la signature de la vérole sur l'œil d'un malade.*" Many endeavors have been made to properly classify the syndromes characteristic of brain syphilis. Huebner in his classic article, divides them into the following forms: Psychical disturbances with epilepsy, incomplete paralyzes (seldom of the cranial nerves) and a final comatose condition of short duration; genuine apoplectic attacks with succeeding hemiplegia, in connection with peculiar somnolent condition occurring in often repeated periods and generally at the same time paralyzes of the cerebral nerves. Lastly, he distinguishes forms with a course similar to that of parietic dementia.

Fournier distinguishes six different forms: 1, the cephalalgic; 2, the congestive; 3, the epileptic; 4, the aphasic; 5, the mental; 6, the paralytic. These classifications have both performed splendid service in the study of cerebral syphilis; but we believe that cerebral pathology has advanced sufficiently to show the relations between certain definite lesions, their location and extent and the symptoms produced by them. So we adopt the following classification: 1. Syphilis of the base. 2. Syphilis of the vertex. 3. Syphilitic endarteritis, which can be either basilar or vertical in situation. 4. Mixed forms, being both basilar and vertical in location and consisting usually of both specific endarteritis and meningitis. 5. Meningo-encephalitis corticalis syphilitica. There are certain general symptoms common to nearly all varieties of brain syphilis. Headache, especially in the earlier stages, is one of them. It is dull and diffuse and is worse at night in some cases. Sometimes it is referred to the vault, at others to the base of the cranium. This is soon followed by insomnia, doubtless due to the continued pain. Vertigo develops in many cases and may be complicated with nausea and vomiting. These patients are morose and irritable. In cases where a syphilitic endarteritis predominates, the patient is just in the opposite condition. He is

drowsy or even stuporous, going to bed early and staying late; those working at sedentary occupations falling asleep at their work. In some cases this state deepens into a veritable coma (Buzzard's syphilitic coma) where the patient can only be aroused by energetic shaking, answers a few questions in monosyllables and on being left alone sinks again into a deep stupor. In some cases the patient is unable to attend to the most pressing demands of nature, such as micturition, defecation, etc. The countenance of the patient often shows a stupid or expressionless aspect, owing to the obliteration of the characteristic lines of facial expression. In many cases of cerebral syphilis we have found pronounced cardiac and gastro-intestinal irritability and a condition of vasomotor paresis of the cutaneous arterioles. These were especially pronounced in cases where there were signs of cortical involvement.

It is known that gummatous meningitis more frequently involves the base than any other part of the brain. The gelatinous exudate is more frequent about the optic chiasm, the interpeduncular space, pons and oblongata, obscuring and enveloping cranial nerve roots. They become infiltrated with the exudate and often the vessels supplying their nuclei become affected, thus producing a thrombosis and softening of them. The cranial nerve palsies of brain syphilis are numerous, but the optic and ocular nerves are especially involved. It is therefore common to meet with ptosis, unequal pupils, strabismus, etc., as a result of the involvement of the third nerve. Involvement of the optic nerves produces contractions and irregularities of the visual field.

There may be a bi-temporal hemianopsia due to involvement of the chiasm, or a lateral or homonymous hemianopsia may be present. In 100 cases of brain syphilis, Uhthoff found the oculomotor involved 34 times, the abducens 16 times, the patheticus 5 times and the trigeminus 14 times. Pupillary disturbances are found, such as the Argyll-Robertson pupil, loss of both light and convergence reflex and the hemiopic pupillary reaction. Optic neuritis of the acute type is often present. Blindness is present in some cases due to excessive pressure upon the optic tract. Neuralgic pains are met with in the trigeminus area or anesthesia or hyperesthesia may possibly occur.

Loss of smell or hallucinations of smell, and loss of taste or hallucinations of taste, occur from pressure upon the olfactory or gustatory nerves, or irritation of their cortical areas by pressure of the specific exudate, at the base. Facial palsy may result from involvement of the facial nerve. Deafness rarely occurs from affection of the auditorius. The roots of the eighth pair of Willis are involved in some rare cases. In many of the mixed cases there are symptoms of involvement of the arteries of the base, due to a concomitant syphilitic endarteritis, especially of those arteries supplying the basal ganglia, the internal capsule, the motor areas, etc. These symptoms are most usually due to thrombosis. The symptoms are very sudden, the hemiplegias and monoplegias developing slowly without loss of consciousness. Another characteristic of palsies of this kind is their ephemeral character, coming and going as the thrombosis caused by the syphilitic endarteritis increases or diminishes. The hemiplegia of syphilis is usually accompanied by oculomotor palsy of the opposite side. The palsies do not occur simultaneously; when they do the presumption is in favor of a non-specific palsy due to a peduncular

hemorrhage. The presumption is usually in favor of syphilis when one attack of hemiplegia is followed by another of the opposite side.

Amnesic and ataxic aphasia are often a complication in these cases, and may be due to either arterial thrombosis or gummata in the sensory or motor speech areas. The same may be said of ataxia or agraphia. Symptoms pertaining to the pons or medulla are often due to involvement of the basilar and vertebral arteries. In syphilis of the vertex we have symptoms which are the result of cortical irritation and showing themselves as attacks of Jacksonian epilepsy. Focal symptoms due to involvement of sensory areas, are occasionally met with. An helter-skelter collection of symptoms pointing to other local or diffuse, destroying or discharging lesions of the cerebral cortex, is often met with in cases of this type. The epileptic attacks are often followed by a paresis of a leg or arm or one-half of the body. Aphasia both of the sensory or motor types or types of bradyaphasia are of frequent occurrence in syphilis of the convexity. In many cases the epilepsy resembles the idiopathic type and simulates the types of grand and petit mal. Another peculiarity characteristic of syphilitic epilepsy is that it suddenly breaks out after middle life and so, as Fournier says, when a patient past thirty years of age suddenly develops epilepsy, it is ninety-nine chances out of a hundred that it is due to syphilis. *Appliquons-nous à démasquer l'épilepsie syphilitique, à peine sera-t-elle connue qu'elle sera guérie*, says Yvaren, and there is no truer saying in medical science.

This class of patients are often morose or irritable or even pronouncedly melancholic. They are, in my experience, the only syphilitics who become maniacal. In some cases we have to deal with a marked disturbance of ideation, apperception and memory. The patients sometimes seem to have their volition impaired, suffering in a marked degree from abulia. When these cases are untreated or improperly treated, the fits increase in number, consciousness becomes more and more beclouded until the patient becomes comatose, involuntarily evacuating urine and feces, respiration and pulse becoming more and more feeble until finally death ensues. In this form of brain syphilis as in many others, we frequently find polydipsia, polyphagia, mellituria and even hemoglobinuria. These last symptoms point to involvement of the bulb. Nearly all cases of cerebral syphilis are accompanied by morbid mental phenomena. The patient may merely have a morbid fear of syphilis or he may become a chronic hypochondriac and imagine that he is afflicted with a new disease every day. The psychoses of weakness or depression are the characteristic mental symptoms in these maladies. Stuporous dementia or hallucinatory confusion are often found in the earlier stages of cerebral syphilis. In the last mentioned variety hallucinations of hearing and sight are especially prominent, particularly the former. The patient may imagine that he hears his neighbors and the public in general speaking about his disease, saying that he is rotten, that he should be shot, drowned or hung. He imagines that on this account he is worthless, that he should be done away with or that his family are conspiring to do so. In some of my cases auditory hallucinations have been among the most persistent and intractable symptoms. In many cases patients who were formerly very neat and tidy became very slovenly and filthy in their attire and

extremely neglectful of all their personal interests. In some of my cases I have also noticed a peculiar weak and bleating tone of voice.

One of the most characteristic cerebral affections of syphilis is a diffuse disease of the cerebral cortex due to a meningo-encephalitis, the so-called syphilitic dementia. That is to say that most cases are due to this definite pathologic condition. Nevertheless, a basilar gummatous meningitis or luetic endarteritis can undoubtedly produce the same symptoms by constricting or occluding the cortical arteries and so producing a diffuse nutritive famine in the areas supplied by them.

Focal and diffuse symptoms are often inextricably mixed. The patient may have transitory attacks of facial, brachial or crural palsy mixed with motor or sensory aphasia, agraphia, alexia or word blindness, and all of these may come or go in a random way. With these are mingled amnesia, abulia, impairment of association and lack of apperception. Somnolence is often present combined with nocturnal headache, made worse by pressure on the skull. Vertigo too is often present. The patient's capacity for exertion is reduced. He is morose and irritable. His face has a stupid and expressionless aspect. He becomes more and more melancholic and soon develops delusions of suspicion, imagining that every one knows and talks about his disease. In some cases suicidal mania develops. Hallucinations of hearing, taste and smell are pronounced. In the writer's experience delusions of grandeur, such as we find in parietic dementia, are pronouncedly absent in syphilitic dementia. Another characteristic is what Erlenmeyer terms the partiality of the defects. Musicians lose their nicety of touch, bookkeepers their power of calculating and artisans their deftness. Only certain mental functions are harmed and others left intact. One of my patients lost his fluency in a foreign language, and his memory for recent events and his volition were slightly impaired. As in nearly all forms of brain syphilis, the disease progresses by jumps, symptoms appearing and disappearing and mixing with new ones. Pathognomonic of brain syphilis is its course, especially in this form, the disease progressing by jumps. Intermissions occur in which the patient is in a state of comparative health or improvement.

Ocular palsies are frequent in many cases, as well as the Argyll-Robertson pupil, mydriasis, myosis, ptosis, etc. We may have amblyopia, optic neuritis, etc. Apoplectiform and epileptiform attacks are common. The delusions from which the patient suffers are unsystematized and the disease frequently simulates the phenomena of parietic dementia, for which it is often mistaken by incompetent diagnosticians. It can easily be distinguished, however, from paresis by the absence of delusions of grandeur and by the presence of numerous focal symptoms occurring in random order. The following phenomena are peculiar to both focal and diffuse forms of cerebral syphilis: 1, sudden shifting of symptoms; 2, the predominance of cranial nerve palsies; 3, the multiplicity of palsies along with their coming and going; 4, the loss of particular accomplishments; 5, the concomitant appearance of symptoms due to destroying lesions of various cortical areas, *e. g.*, left hemiplegia with aphasia or brachial or crural monoplegias, etc.; 6, the sudden coming or going of apparently fatal symptoms such as coma, followed by perfectly lucid states; 7, the comparatively rapid termination in dementia. In the

treatment of brain syphilis there are only two sheet anchors: mercury and the iodids. The writer uses mercury in the form of an inunction, rubbing in from one-half to one dram daily for a period of about three weeks. I intermit this treatment when salivation appears, which can be greatly retarded by carefully cleansing the teeth every three hours. I no longer torture my patients by giving them the ordinary iodids of potassium or sodium, for I have never yet seen a single patient who could tolerate the enormous doses of these salts which we find necessary to give in cases of nervous syphilis. I find their administration to be followed by great anorexia, headache, malaise, diarrhea, coryza, cutaneous eruptions, etc.

But the iodids are necessary in some form, owing to their destructive action upon luetic exudates and their stimulating action upon the lymphatic and glandular systems. So, for the last three years I have been using, with most gratifying results, the excellent syrup of hydriodic acid made by Mr. R. W. Gardner of New York.

There is no preparation more widely substituted than this by unscrupulous druggists, but in my experience no other preparation has had the same beneficial results. It agrees well with the stomach and can be given before meals, when it can best be absorbed. It can be continued for a long time without producing symptoms of iodism and yet is just as efficacious as the salts of sodium, potassium, etc. Robust patients I am in the habit of putting upon a spare diet in order to facilitate destructive tissue change. I also have them drink plenty of water and take a hot air or water bath in order to increase the excretory functions of the skin and kidneys. Anemic or weak patients are to have a plain but nutritious diet. The use of inunctions should only be resumed at the end of two or three weeks after the appearance of stomatitis. The syrup of hydriodic acid I give continuously. After a certain length of time I give the patient a tonic course of iron, strychnin, arsenic, quinin, cod-liver oil and hypophosphites and mercauro. Half-way measures are of no avail in the treatment of brain syphilis. Yvaren has well said that our treatment must be as energetic as the disease. The physician should first make sure of his diagnosis, then map out his line of treatment and stick to it with bull-dog pertinacity. Pursued in such a manner as this, no disease can give more gratifying results in its treatment, than brain syphilis.

TREATMENT OF URETHRAL STRICTURE.

BY FREDERICK LEUSMAN, M.D.

CHICAGO, ILL.

It is not here intended to speak of the expedients and methods called for by cases of emergency rendered singular by the rarity of their occurrence as well as their complications. For all practical purposes we have three accepted forms of treatment: Dilatation, electrolysis and urethrotomy.

True, we have an Oberlaender, who with a dilator that bears his name dilates the urethra and controls the effect of this procedure with the endoscope, and we have a Tuttle with a dilator of his own. There is the famous Guyon, who, with a syringe named after him, and an elongated nozzle, injects medicines into areas assumed to be the seat and cause of the disease. More workers with methods and appliances might be mentioned, bound to give some returns in the hands

of a thoughtful, skilled surgeon, ably seconded by an obedient patient. But correctly or incorrectly, while these gentlemen are justly classified as authorities in their chosen lines, their practice finds few imitators in the profession, as a whole, either in hospitals, clinics or private practice.

It is curious to retrospectively view some of the remedies and modes used in days gone by, such as slippery-elm tents, horsehair, hydrostatic dilatation, quadrangular sounds, Holt's divulsor, cauterization with potassa fusa.

Henry Thompson narrates an instance in which a surgeon passed a caustic 486 times during six years, seconded by the daily introduction of a bougie, which was left *in situ* for half an hour. The patient, so it was claimed, continued free from relapse. Another case required twenty-two years for cure. E. Home published a case where a caustic had been applied 1258 times. Honor be due to both surgeon and patient. Thielman¹ recommends the internal use of potassium iodid.

Even in these days many efforts are made to cure organic stricture and its attendant symptom, gleet, with internal remedies, injections, gelatin bougies and other hobgoblins too numerous to name. The patient must swallow sandalwood oil, copaiba balsam and other drugs that furnish but little palliation, and certainly no cure, but irretrievably damage the tender cells of the uriniferous tubes in his kidney, and the no less delicate cells of the mucosa lining his stomach. When at last the stomach or kidneys rebel, injections are ordered for a change. That in the nature of things also failing, a small sound is passed, also with no relief, until the patient tires and goes from doctor to doctor, with some kaleidoscopic changes but no cure. Even the bacteriologist, armed with centrifuge, immersion-lens, culture-tube, rabbits and the authority that a position in the laboratory apparently conveys, is unable to draw valuable or practical conclusions by means of his scientific paraphernalia. The patient leaves the bacteriologist entertained and edified but not cured. W. Bruce Clark² says: "If we would gain a clear knowledge of the best methods of treatment, we must extend our knowledge of pathology from the museum spirit to the human flesh, which is more than ever possible today by the aid of the urethroscope and cystoscope. What up to quite recently has been a matter of supposition and inference is today often visible to personal inspection. Once a stricture, always a stricture, represents the views of twenty years ago. Rectal strictures of a fibrous nature certainly yield to free division, accompanied by persistent dilatation subsequently, and if large bougies are used for a year, at first daily for ten minutes, and after a few months less often, the stricture disappears and shows no tendency to return, a fact which I have been able to verify on several occasions." The idea that strictures can be cauterized away by means of potassa fusa, etc., is happily antiquated. The benefit occasionally received from such treatment must be attributed to removal of tender spots and the incidental dilatation. The man who treats gleet with injections finds his congener in the man who treats nasal catarrh with washes and sprays only.

Before proceeding to local treatment we must appreciate the necessity to arrive at a thorough understanding of all underlying causes so as to be enabled

to direct the hygienic, dietetic, moral and constitutional treatment accordingly. Be on the lookout for complications, and bear in mind the ever-present enemies such as syphilis, tuberculosis, uric acid diathesis, polypi, granulations, in brief, make a wide-gauge diagnosis. Life is too short, opportunities too limited, cases too varied to allow any one man to speak the last word as to what method is the best in a general way. Probably in the nature of things there is no such generally successful and always applicable procedure. The individuality of the patient, as well as his attendant, will reassert itself. Some patients will submit to anything rather than the knife; some medical gentlemen entertain an equally wholesome horror for the keen edge of the blade, while again we meet with the resolute patient who is tired of compromises, and the resolute surgeon with confidence in his art, who will cut the stricture. Besides, other considerations frequently enter, which in practical life sweep away all theories and opinions of even the authorities. The very interpretation of the case, the diagnosis, whether or not certain symptoms result from a stricture or not, will frequently be ushered in only after prolonged labor pains. It has been perhaps justly claimed that all the good that ever came out of any of these means is mostly due to the incidental dilatation. The therapeutic or remedial effects of the passage of the sound may be classified as follows:

"1. The allaying of urethral hyperesthesia.

"2. The restoration of the urethral canal to its normal caliber and the absorption of inflammatory products.

"3. By expressing the contents of the suppurating urethral glands and lacunæ, it exerts a curative influence."³

Almost all modern authors agree on the value of dilatation and the ease of its application. In accordance with their teachings the large majority of surgeons and physicians in their daily practice dilate their patients' strictures, unless the strictures give rise to difficulty in urination, when, other conditions permitting, the surgeon will cut and the physician still get along with filiform bougies, aspiration, continuous dilatation, rest, heat and baths, eventually bringing his patient's stricture to a caliber that will admit metallic sounds. I will pass over Guyon's irrigations, endoscopic applications and examinations, for they come into play only in the absence of stricture, and in the presence of stricture only when stenosis is complicated by granulations, polypus, chronic localized catarrhal conditions and ulcers that will not yield to the use of the knife and sound.

Strictures that are not organized beyond all hope of resorption will frequently be cured by intelligent and patient efforts at sounding. To do that effectually requires in many cases meatotomy. This little operation I have found has difficulties of its own. We must cut enough, but beware of over-cutting and remain in the center, cutting a part and relying on the bougie *à boule* to tell us whether to stop or continue seems the safest way. Hemorrhage out of all proportion to the operation is apt to occur primarily or secondarily for a week or more after. The insertion of horsehair sutures for the approximation of the urethral mucosa to that of the glans has been recommended as a preventive measure of this very annoying complication. There is a general agreement that sounding should not be repeated till all the

² London Lancet, iv, 137-149.

³ Stewart: Diseases of the Urethra.

reaction caused by their use has disappeared. The interval will thus vary from three to five or seven or more days, depending on the character of the case and rapidity of increase in the size of the sound used. The length of time that the sound should be allowed to remain will also vary with this modification, that the oftener sounding seems advisable the less time should they be permitted to remain within the urethra. When sounding is done at less frequent intervals, every two to four weeks or so, ten to fifteen minutes duration has proved in the writer's experience not to be any too long a time. It is axiomatic to always remove the sound when the pain attendant upon its introduction in place of dying away increases in severity. Extreme distention long enough applied, frequently repeated, results in a thinning out of these fibrous bands and finally snaps them to pieces, when they are ultimately absorbed. That this result frequently happens and follows the exertions of a conscientious physician assisted by a faithful patient, there can be no doubt. The clinical result is meant, and not the microscopico-anatomic one that the pathologic anatomist will bring before our vision in instructive serial sections. Surgery even of the mildest kind, such as sounding, causes cicatrices of its own. Surgery can not be done without cicatrix formation; still surgery in modern times furnishes the greatest clinical results. Thus if success attends our efforts at dilatation, if the stricture is gradually melting away, if the symptoms disappear, if recontraction, even after putting intervals of months between the soundings, does not take place, then the physician can claim a cure, and such cures must be frequently obtained if we believe the testimony of the great surgical writers of the day. But if in the presence of a well organized stricture the patient is not willing to put in a year or five years' sounding as an experiment as to whether this mode of treatment will cure or not; if, further, in the judgment of the surgeon the case seems one unsuitable for sounding alone; if time is an object and the most rapid way, most promising in results is sought after; if the patient is willing to be treated for one year only, but not ready to carry his sound in his portmanteau and thus carry on treatment to the time of his grave; if the surgeon is aware that a bladder is better off without life-long instrumentation with its dangers of vesical and renal infection; if, further, the patient has been sounded by a half dozen physicians with no relief from symptoms, then under such and other conditions it becomes our duty to cut; by cutting the ring or rings of fibrous tissue at one point we can now introduce properly-sized sounds, reach extreme dilatation, get absorption and produce a clinical cure. Otis' urethrotome in narrow-caliber cases, preceded by Maissonneuve's instrument, is the best and last device in the progress of evolution. It is a combination of dilatation, divulsion and cutting. The difficulty of properly cutting a stricture, of dividing the last fibers, will be realized when you test your case ten days later with a bulbous sound of proper size and find a stricture where everything appeared free after cutting ten days before. If stricture in such cases be still present, it must be cut again (Otis); you must follow strictured fibers as relentlessly as infection in carcinoma or tuberculosis.

Sounding after cutting has to be maintained for one year, once or twice a week in the beginning, and in the end the interval is lengthened to once a month.

The patient must be informed before submission to the operation that he has to remain under your care for one year, or else his second condition will be worse than his first. But if he be a man determined to get rid of a filthy, enervating affection, he will gladly submit to one year's treatment. He is then done with sounding and troubles referable to that part of his economy. With aseptic care there is no danger from cutting; no danger at all compared to the dangers incidental to the presence of the stricture. An annoying, but, in my experience, never dangerous feature is hemorrhage. But given a patient who follows instructions and is no hemophile, the writer has usually controlled all bleeding promptly by means of pressure applied externally and rest in bed with elevated pelvis.

Clifford Perry,⁴ at the suggestion of Maisch, has successfully stanchd the hemorrhage following an incision in an alveolar abscess of a bleeder by the internal administration of calcium chlorid. This was given in 1.30 gram doses every four hours, and with magic results. Sounding is begun the third or fourth day after operation, and made painless by means of cocain anesthesia. The urine is rendered non-irritating and the nervous system tranquilized by a solution of potassium citrate and bromid. The addition of secale cornutum lessens the disposition to hemorrhage. Some patients will attend to their business the next day, but it is a good rule to confine them to their bed or couch for a week or two. The average patient is able to be about in from three to seven days.

There is no question of choice between internal urethrotomy and perineal section; the latter operation is the only one suitable in strictures posterior to the anterior layer of the triangular ligament. Perineal sections should be supplemented by anterior internal urethrotomy if necessary. Abner Post remarks: "We may consider strictures as to their effect upon life and as to curability of the local lesion. A very important point in prognosis is the extent to which the kidneys have suffered, a matter by no means easy to determine in every way. Some evidence of their conditions can be gained by careful examination of the urine, noting the quantity secreted and the amount of urea and albumin, even when the amount of pus makes microscopic examination difficult. The condition of the heart ought also to be considered, as it is affected by renal disease of varied origin." E. H. Fenwick has drawn attention to the amount of residual urine in cases of stricture as of value in estimating the damage to the kidneys, by showing the amount of pressure the kidneys have been working against. It may be safely assumed that five ounces of residual urine, which is probably near the average of unreleased narrow strictures, would indicate sufficient damage to cause anxiety as to the effect of any intercurrent inflammation or disease, while an amount over ten ounces would make us cautious in operating for stricture by internal urethrotomy and in giving anything but a grave prognosis of the ultimate effects of the constriction. The behavior of the bladder in its progress in regaining the power to completely empty itself will teach us much as regards the future course of the case. It is a great advantage to perform this operation under the influence of a general anesthetic, for a number of reasons, not the least of which being the opportunity it affords of investigating the rectum and to do such rectal surgery at the same time as the exigencies of the case demand.

⁴ The Journal of the Amer. Med. Association, March 18, 1897.

The treatment of electrolysis is carried out mainly by physicians of non-surgical tendencies. That it has done good in the hands of such men as Newman of New York, we can have no doubt. Failure to obtain results should be charged up, not so much to the method as to the operator. This statement applies with equal force to the cutting operation and dilatation without previous urethrotomy. We must remember that others may accomplish what we do not, and when we compare methods, we usually are experienced only in one or the other way: for the balance, we are compelled to be satisfied with reasoning *a priori*. Keyes⁵ says: "I believe that a strong current is full of danger, both immediately from irritating effect and ultimately from cicatricial effect, and that employment of the negative pole does not prevent this. My study of the subject and the experience it has brought me, digested with all the impartiality I possess, led me to state that the allegation that electricity, however employed, is able to remove organic urethral stricture radically lacks the requirement of demonstration. The confidence of its advocates that it will radically cure organic fibrous stricture is, in my opinion, due to the combined credulity of the patient and imagination of the surgeon, or to some special but fortuitous act of Providence upon the co-operation of which, in the case of his own patients, the general practitioner can not with any confidence rely."

CONCLUSIONS.

1. Dilatation is the best treatment in strictures if it cures.
 2. Electrolysis is a modified dilatation; it is a good treatment unless contra-indicated.
 3. Cutting is the cure in non-dilatable cases, and in all strictures at or near the meatus.

THE RECLASSIFICATION OF SOME ORGANIC NERVOUS DISEASES ON THE BASIS OF THE NEURON.*

[ABSTRACT.]

Presented to the Section on Neurology and Medical Jurisprudence, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY CHARLES K. MILLS, M.D.

A few neurologic writers have already spoken of organic neuron diseases, and many views and theories, as well as a considerable terminology springing from the doctrine of the neuron have rapidly been developed.

The most important point of the present communication is to direct attention to the fact that the time has arrived for applying the theory of the neuron, or the nerve cell regarded as an anatomic unit in the classification of some of the most important organic nervous diseases, and especially many of those which have been hitherto placed under such heads as system diseases and primary degenerations.

In a general way, the diseases to which I shall chiefly refer may be classified under the three heads of *tox-*

mias, *inflammations* and *primary degenerations*, but more especially the last. In a fundamental sense they might probably all be classed as toxemias, since the chronic scleroses and degenerations, as well as various recognized forms of peripheral and central inflammation are primarily due to a toxic cause, using here the word toxic in its broadest sense.

Accepting the classes of toxemias, inflammations and degenerations, many of these would be better grouped as neuronal or neuron diseases, rather than as diseases of the brain, spinal cord or of the peripheral nerves, as they have usually been designated.

Not only do toxic agents resulting in inflammations and degenerations tend to attack special systems of neurons; but not infrequently a selective tendency is exhibited as regards the sensory, the motor, the intercalary, or the association systems of neurons; and more than this, special portions of the motor, of the sensory, or of the intermediate chain of neurons are liable to be attacked in particular instances, while other portions of this particular system escape. The facts at our command are chiefly with regard to the sensory and motor projection systems, but the evidence is accumulating that in particular cases commissural, associating and storage systems may also be liable to elected system diseases.

The term "system disease" is one which has long been in use in neurology. Commonly it has been applied to those diseases of the neuraxis, and especially of the spinal cord, which attack, or are supposed to attack, exclusively certain tracts or regions of nerve fibers or nerve cells having common anatomic relations and physiologic properties. It is, however, more scientific and more helpful practically, to consider system diseases from the basis of the neuron, than to regard them as diseases of the cord or of the brain.

One point to be strongly emphasized incidentally is that the toxic agents tend primarily to attack systems of neurons as a whole, and not this or that particular part, as the cell corpus, the axon, the collaterals or terminals. It is true, however, that the destructive influence of the poisoning agent may be first exhibited, so far as can be learned by the means of investigation at our command, in one or in another portion of the nerve cell.

Dr. Spiller and the writer have recently made a study of acute ascending paralysis (Landry's paralysis), in the case of a patient who died in the wards of the Philadelphia Hospital¹. A careful postmortem examination was made, this including not only an examination of the organs in general, and of the central nervous system, but also that of some of the motor and sensory nerves. The conclusions reached in this study are of interest in connection with the views here presented. Both the peripheral nerves and the cell bodies were the seat of extensive degeneration.

It has been held by some that in multiple neuritis it is presumable that the poison acts on the entire sensory neuron at the same time, which accords with the views of the writer that in most neuron diseases of toxic origin the poison tends to attack the neurons elected as a whole.

The disease which has so long been known by such names as locomotor ataxia, tabes, tabes dorsalis and posterior spinal sclerosis needs, from the standpoint of the neuron, to be presented in a new pathologic light, but I can not review here the recent literature of this sub-

⁵ New York Med. Jour. Oct. 6, 1888.

*The substance of this paper was read before the William Pepper Medical Society of the University of Pennsylvania, March 11, 1898; and before the Baltimore Neurological Society, April 20, 1898; and was presented to the Section on Neurology and Medical Jurisprudence of the American Medical Association in June, 1898, as above indicated. Just before sending the paper to the last named meeting I received a copy of a work by J. M. Gerest, entitled "Les Affections Nerveuses Systematiques et la Theorie des Neurones," 1898. The author of this work takes in many respects the same points of view as the writer.

¹ Mill, C. K., and Spiller, W. G.: See Jour. of Nerv. and Ment. Dis., vol. xxv, No. 6, June, 1898. The paper giving the results of this investigation was read at the meeting of the Am. Neurolog. Assoc., held in New York, May 26, 27, 28, 1898.

ject; indeed, this is not the purpose of the present contribution, which is rather to present broad suggestions regarding neuronie classification. Using terms as we now commonly employ them, tabes, like other diseases to which attention will presently be directed, is neither purely spinal nor purely neural, neither purely central nor purely peripheral; but it is an affection primarily of sensory neurons or nerve cells, and Langdon², with others, has very properly suggested to regard it as a "sensory neuron degeneration." "As a result of predisposition, hereditary or acquired, and the action of a toxin or toxins (left by a preceding syphilis, usually though not invariably), the nutrition of the nervous system as a whole is lowered. In certain groups of sensory neurons (muscle sense, iris reflex, optic nerve), the impairment is greater or the resistance of the tissue is less, and in these groups degenerative changes occur."

Tic douloureux and some of the forms of primary degeneration which single out the olfactory, optic, cochlear, vestibular and glossopharyngeal nerves should, in the opinion of the writer, be classified with tabes as sensory neuron degenerations.

Let us now, in the development of the same line of thought, turn our attention to some of the well known forms of "sclerosis" and "degeneration."

Most authors still content themselves with describing the pathology of ataxic paraplegia as sclerosis attacking the lateral columns and part of the posterior columns, the posterior root zones usually escaping disease. The lesions in the so-called spinal form of hereditary ataxia differ from those of acquired ataxic paraplegia in that the lesions are more extensive and involve the posterior root zone in all regions of the cord, and the whole of the posterior columns except the small region to the inner side of the neck of the posterior cornu, the direct cerebellar tract being also involved. It would be better to class these diseases as instances of mixed neuron system degeneration. We have in them degeneration beginning both in the sensory neuron systems and in the motor neuron systems, and in the case of hereditary ataxia involving additional special systems.

In amyotrophic lateral sclerosis the parts early invaded are the terminals and collaterals of the cortical motor neuron, and later the ganglion cells of the ventral horns. Both the direct and crossed pyramidal tracts and some of the systems of short fibers in the lateral columns, as well as the cells of the ventral horns, have been found degenerated in careful postmortem examinations. Somewhat frequently in this disease the nuclei of the cranial nerves and the pyramidal tracts in the oblongata and pons are implicated in the degeneration, and in rarer cases this has been traced upward to the peduncles, and even to the motor cortex. In extremely rare cases even the cells of the motor cortex have been found to take part in the disease. It is not improbable that implication of the entire extent of the cortical motor neuron will be more frequently found when the present methods, advanced as they are, are improved and investigations are more complete. The disease is in reality one attacking two systems of neurons, and at least one of the names used as descriptive of it should indicate this fact.

Those forms of progressive muscular atrophy, either acquired or embryonal which presumably have their origin in the nerve cell, should be classified under the head of motor neuronal degeneration, and then sub-

classified according to their position and extent. Bulbar paralysis should also be classified under motor neuronal degenerations, and subclassified according to the special cranial nerve system involved. More or less generalized cranial motor neuronal degenerations would include the different types of bulbar paralysis; and motor neuronal degenerations of special nerves would give such well known affections as lingual atrophy, facial atrophy (here including painless tic), and the atrophic ophthalmoplegias.

The so-called "primary lateral sclerosis" is something of a stumbling block in our efforts at neuronie classification. According to views long accepted, in this affection the lesion is a degeneration or a sclerosis of both lateral columns, usually beginning in the white matter of the lumbar cord and subsequently passing up the cord, but without involving the cells of the ventral horns. In other words, according to this view we have a primary degeneration attacking and confining itself to the processes of the nerve cells. While this disease has, however, long held its place in the nosology of nervous diseases, only an exceedingly limited number of autopsies *apparently* uphold the pathology above indicated. The probabilities are altogether against the idea of a true primary lateral sclerosis; and the cases which present the well-known symptomatology of this affection can probably all be otherwise relegated, as to Erb's spinal paralysis, amyotrophic lateral sclerosis and hysterical spasmodic paraplegia.

The application of the theory of the neuron to classification is most readily made in the case of the degenerative diseases, and yet the same truths are applicable to diseases which more rapidly run their course, as overwhelming toxemias or active inflammations. In Landry's paralysis the peripheral motor neuron is attacked and largely destroyed. In poliomyelitis, both of the infantile and of the adult type, in the polio-encephalitis superior and inferior of Wernicke, and in the cortical polio-encephalitis of Strümpell, motor neuron systems are attacked. Much controversy has taken place as to whether in multiple neuritis the affection is primarily one of the peripheral nerves (that is, of the axis cylinder processes), of the cell bodies, or of both. Much evidence, clinical and pathological, is certainly in favor of the view that polyneuritis in many cases is a true peripheral disease; but in many other cases those forms of inflammation which are usually designated as neuritis and as poliomyelitis involve the entire neuron, and not simply the peripheral nerve (in the ordinary acceptance of the use of the word "peripheral"), on the one hand, or the cell bodies in the ventral horns on the other. Those forms of so-called polio-encephalitis and polyneuritis which have been most studied are now almost universally conceded to be either of infectious or toxic origin. With regard to multiple neuritis it is no new thing for me to teach the involvement of both nerve and cord in a large number, if not in a majority, of the cases. Long before the theory of the neuron was thought of, I expressed my belief that in many cases of so-called multiple neuritis both periphery and spinal centers were implicated, in other words, as then expressed, we had a concurrence of multiple neuritis and of generalized poliomyelitis in the same case. Several recent investigators have shown involvement of the posterior roots and even of the entire sensory and motor neurons both in multiple neuritis and in cerebrospinal meningitis. Long ago I also

recorded clinical observations on cases of multiple neuritis which eventually became cases of true tabes. Cases of poliomyelitis with implication of the peripheral motor nerves are also on record.

These diseases are, therefore, in some cases at least, neither instances of neuritis in a strict sense or of poliomyelitis. They are perhaps what might be termed "neuronitis," and this term has been suggested, but seems to have an unnatural sound even to a neurologist.

While the facts which point to the importance of reclassifying certain diseases on the basis of the neuron are clear and convincing, it is difficult to determine on a simple and practical method of doing this. It will probably be best for clinical reasons to arrange these diseases in the first place under the heads of *embryonal* and of *acquired neuronal diseases*, and then to subclassify these according to the particular system or systems of neurons attacked. This subdivision would include (1), diseases of the sensory neuron systems; (2), diseases of the motor neuron systems; (3), diseases of both sensory and motor neuron systems at the same time; (4), diseases of intercalary or associating systems of neurons; and (5), diseases in which numerous systems of neurons are more or less indiscriminately attacked. The fourth and fifth categories will receive only passing attention in this paper. Within these groups an effort could of course be made to subclassify toxemias, inflammations and degenerations, but this will not be attempted in the present paper, and perhaps it would not answer any useful purpose to make the attempt. By far the larger number of neuronal affections are perhaps to be classed under the general head of primary degenerations, at least with our present pathological knowledge; but toxemias and inflammations which do not lead to degeneration are also, as I have already indicated, to be included.

Every thinking neurologist has felt the importance of having some good method of classifying under some general head the numerous hereditary or family affections. The theory of the neuron offers us one of the best methods of doing this. The embryonal or family diseases can be classified with some approach to success under the different physiologic systems of neurons. Under primary embryonal degenerations of motor neuron systems, for instance, such affections as Little's disease, and perhaps other forms of infantile diplegia or hemiplegia, and some of the forms of juvenile muscular atrophy might be grouped; under embryonal degenerations of sensory or of mixed sensory and motor neuron systems might be included Friedreich's ataxia, hereditary cerebellar ataxia, and the common type of syringomyelia; and under special forms of embryonal neuronal degenerations could be classed amaurotic family idiocy, so-called Huntingdon's chorea, for which Halleck has suggested the name of *dementia choreica*, and even perhaps some of the special types of the insanity of developmental periods.

Amaurotic family idiocy is a type of affections in which numerous systems of neurons are arrested in their development, while general paralysis of the insane is a type of acquired disease in which numerous systems of neurons are more or less indiscriminately attacked. Hirt, by classifying this disease under the head of general diseases of the nervous system, recognized the importance of taking it from the category of cerebral affections or of ordinary insanities.

Provisionally the views expressed in the previous pages might be in part summarized in tabular form as follows:

EMBRYONAL NEURONAL DEGENERATIONS.

- I. Sensory or sensorimotor types. 1, Friedreich's ataxia; 2, hereditary cerebellar ataxia; 3, syringomyelia.
- II. Motor types. 1, spastic diplegia (some types, as Little's disease); 2, progressive muscular atrophy (some types).
- III. Mixed and multiple types. 1, amaurotic family idiocy; 2, dementia choreica (Huntingdon's chorea); 3, developmental insanity (some types).

ACQUIRED NEURONAL DEGENERATIONS.

- I. Sensory types. 1, tabes; 2, tic douloureux; 3, primary degeneration limited to nerves of the special senses.
 - II. Motor types. 1, progressive muscular atrophy (some types); 2, amyotrophic lateral sclerosis; 3, progressive bulbar paralysis; 4, primary degeneration of particular motor nerves, as of the hypoglossal, facial, trigeminal and ocular.
- For the present it will perhaps be best to place neuronal inflammations and toxemias in a special class, including, 1, acute ascending paralysis (Landry's paralysis); 2, anterior poliomyelitis; 3, polio-encephalitis superior and inferior of Wernicke; 4, cortical polio-encephalitis of Strümpell; 5, multiple neuritis and neuromyelitis.

HOW DOES THE CAUSE OF DISEASE PRODUCE DISEASE? A NEW INTERPRETATION OF OPERATIVE PRINCIPLES.

BY W. R. DUNHAM, M.D.

KEENE, N. H.

The following direction of research was suggested by J. M. DaCosta, M.D., LL.D., in his address before the Association of American Physicians, at Washington, D. C., May 4, 1897: "The great advance of our time it seems trite to say, is the ardent study of the causation of disease. And often what we consider the cause, may thus be only the consequences of disease. The soil and the forces, too, are to be studied and critically examined."

There has been much written respecting the soil of disease, while it is a new suggestion that we critically study the nature of the forces which present disease phenomena. And with such review it may be well to mention, that the science-mind for many generations has been satisfied with the interpretation, that forces from without, that active medical principles and active causes of disease in addition to active vital forces, have taken part in the operations presented by the living human organism, while of recent date the more advanced thinkers deny that supplementary forces can be introduced to operate the machinery of life. Such expectancy, however, has prevailed for a long period and will doubtless be slow of elimination until a clear comprehension is developed respecting the nature of the vital forces.

A distinguished editor of an American medical journal states, as late as January, 1898: "There is no drug yet discovered, unless it be alcohol, which adds to the forces of the body." But even this one source will be discredited when it is recognized that medico-biologic science is based entirely on the functions and operative principles of the vital force energies. Thus in the near future a different operative plan of medical science will be taught in the schools, effecting as great a revolution of ideal *modus operandi* as was experienced in the acceptance of the Copernican interpretation of astronomic plan. Therefore, in place of teaching medico-biologic science as being based on functions and operative principles, derived from both within and without, this division of natural science will have its recognized first principles begin-

ning with a comprehension of the nature of the vital force agency. But in making research for the discovery of such primary principles we shall be required to differentiate between the functions of the several ultimate active divisions, which enigma has never had a pretense of solution from the many teachers of medico-biologic science. And furthermore, we shall be confronted with high authority alleging that the mind can not grasp the nature and ultimate functions of the vital force agency. That distinguished authority, Henry Maudsley, M.D., F. R. C. P., states: "It is easy to perceive how impossible it is in the present state of science to come to any positive conclusion in regard to the nature of vital force. This, generation and generations to come, will have passed to their everlasting rest before a discovery of the secret of vital activity is made." Notwithstanding such statement, the vital force problem as implied in the operative plan of its several ultimate principles is already solved, and is no more difficult to comprehend than the Copernican plan of astronomic science and may be as positively demonstrated. The fact is, the cultured mind is so well satisfied with the long accepted interpretation that active principles from without may be introduced to operate the human organism, that little or no desire is experienced for the making of research, for exercising original thought, to discover the operative plan of the vital force function. And it is only of recent date that a review of the alleged situation has been suggested.

It has always been difficult to eliminate ideal errors of long acceptance, which is most significantly illustrated in the incident, that such entire satisfaction prevailed with the Ptolemaic interpretation of astronomic plan, that it required more than one hundred years to develop a comprehension that any scientific advantage would result from a review of the alleged situation. And it is a fact that can be demonstrated, that the medical science mind has committed a far more serious error of interpretation of operative plan than was perpetrated by the ancient astronomic investigator, which lamentable misfortune is not generally known.

Says Dr. Lionel S. Beal, M. B., F. R. C. P. Lond., F. R. S., in the London *Lancet*, May 24, 1896: "I am particularly desirous of directing attention to the question of vitality just now because during the past year there have been indications of a change of opinion, and the prospect of obtaining a patient hearing is better than it has been for thirty or forty years. Vitality is a distinct force and every pathologic change is directly consequent upon vital action." Rudolph von Virchow, M. D., in his address before the International Medical Congress in Moscow, 1897, stated: "I freely confess that the seeking of the point at which medicine begins to form a part of biology has been one of my fads; hence I have devoted the last days of my life to establish and spread the idea that pathology should be considered a branch of biology. This is natural, but the delicate point is, in order to realize it in a precise manner, how to establish the relations uniting life with disease." A patient research in this direction will certainly reveal to the comprehension that active vital functions constitute all the "active principles" that may operate the living human organism in health and disease. Consequently, the doctrine as now taught, that some mysterious active principle is introduced from without in association with the cause of disease, that acts to produce

disease, in other words, that forces from without, forces not vital, attack the human organism, is an error of great and serious magnitude. Therefore, to understand how the cause of disease produces disease, it will be necessary to first comprehend the special functions of each ultimate operative vital principle, and the co-operative working plan for the presentation of the two grand divisions of life activities, voluntary and involuntary, both health and disease being manifested by the department of involuntary activity.

To comprehend how the involuntary organism is set into that special disturbance constituting disease, we must examine the working plan of ultimate vital functions, normal and abnormal. And in seeking the solution of the vital force problem implied in the *modus operandi*, we will consider first the special function of each ultimate life principle, as expressed in the terms, sensibility, instinct, sensation and contractility; and later, the co-operation of said functions.

Sensibility, the mind function, relates the individual to the external world and superintends the voluntary acts, using the life principle contractility to execute voluntary motion. Among the numerous subdivisions of this department there may be included the ability to think, reason, originate ideas and experience a variety of emotions.

Instinct is that life function which superintends all involuntary acts comprised in organic construction and structural repairs; using food material and eliminating waste and foreign material. Instinct is a life function but not a mind function, a distinction to be ever recognized, while sensibility is both a life and mind function.

Sensibility can not execute the functions of instinct, nor reversely.

Sensation is an operative life principle entirely different from the two departments mentioned. It is a life function but not a mind function, and is the life principle which relates the organism to the contact world, while sensibility relates the individual to the external world. Sensation is a life principle of great magnitude and importance to consider, in fact a department that would require much time to describe, entering into a vast multitude of obscure life problems. Among the numerous subdivisions of expressed special functions included in this division may be mentioned taste, smell, heat, cold, itching, pain and all degrees of irritability, which last term includes a great variety of disagreeable sensations. Sensation is a life function expressed from relations of contact, and is manifested by the entire human organism, while sensibility is manifested only through the brain.

Contractility is the life principle that manifests animal strength and executes motion, and is the vital principle exercised by the mind for presenting voluntary motion, and by the instinct in the presentation of involuntary activities.

The foregoing terms, which represent the distinct departments of ultimate operative life principles, are not of new coinage, but have ever been attended with the great misfortune that no practical distinction has been recognized and taught respecting the special function of each department, and their co-operation as expressed in the complex affairs presented by the living human organism, while it is not possible to understand the nature of vital force until we first distinguish the difference between such operative functions and determine what each department executes as a life act. Thus a knowledge of such functions consti-

tutes the starting point of thought in medico-biologic science. In other words, we can not explore thought regions existing as transpiring events prior to the manifestation of such special principles of life expression. And we must recognize, also, that the nature of vital force is implied in what those functions execute, normal and abnormal.

While distinguished authorities allege that the vital force problem is impenetrable, such is not the fact, and this belief is perpetuated because the mind has failed to discover that any practical knowledge may be acquired from a recognized distinction of function, as executed by the four mentioned departments of operative life principles, a department easy to comprehend and demonstrate. Consequently, from this omission of distinction the terms sensation and sensibility are used synonymously without any apparent clear idea of their precise application. Some text-books allege that the skin is the organ of sensibility and the brain of sensation, while the late Thomas H. Huxley has committed a similar error in attributing to the skin the function of sensibility and consciousness. The function of instinct is also confounded with that of sensibility, and nearly all writers give credit to that life ability called instinct, for the exercise of both voluntary and involuntary activities; and no practical distinction appears to be recognized between instinct and innate intelligence.

After the thoughtful mind has made original research and become satisfied that the four mentioned divisions of alleged operative principles really exist, and mean something in each, executing a function peculiar to itself, it will next be important to consider the working plan of co-operation, in other words, the *modus operandi* for the presenting of the two grand divisions of life activities, the voluntary and involuntary. The following is suggested as the real plan, and is easy of demonstration: That voluntary acts are exercised in response to the mind, while involuntary acts are exercised in response to sensations. In illustration, sneezing is an involuntary act executed in response to a sensation.

The alleged reflex act executed in response to stimuli, or irritation, which language is slightly misleading, represents a similar operation to that implied in the phrase: "Involuntary vital acts are exercised in response to a sensation." A sensation is a primary expression of life principle. There has been no previous action for its development, but merely a passive contact. Thus the term "reflex action" is not the correct language for the best explanation of the event. The irritability of a nerve is not an action on the nerve, but an expression of contact relation by the nerve, as a previous condition that may determine whether a physiologic or pathologic vital act is to succeed.

The conditions called health and disease are each presented or executed as involuntary acts in response to existing sensations, normal or abnormal. There are problems in medico-biologic science that require a clear mental perception, not the microscope, to effect a correct solution.

In accordance with the operative plan of the vital force agency, it is to be recognized that the mind directly superintends voluntary activities and indirectly superintends, to a limited degree, involuntary life acts, by developing such special sensations from contact relations as will be succeeded by the kind of involuntary act that it is desired to have established,

or set into special operation. Consequently, medicine is useful, not because of an associate active principle, but as the means from a relation of contact for the developing of special sensations. The idea that medicine acts is misleading; there is no medical power, but medicine causes special sensations in response to which involuntary life acts are exercised.

When we comprehend that physiologic acts called health, succeed to normal sensations, and pathologic acts called disease, succeed to abnormal sensations, it then becomes easy of solution as to how the cause of disease produces disease. The contact of the cause of disease produces abnormal sensations in response to which pathologic vital action is exercised, and this pathologic act in itself constitutes active disease. There is no "active principle" except pathologic vital action associated with disease problems. While this interpretation of operative plan may be easy of demonstration, there is something more than intellectual pride to be considered in association with this view of the situation. The present doctrine that "active principles" from without may be introduced to operate the machinery of life, opens the door for the ignorant to practice medicine, even to the satisfaction of the large majority who have been thus educated. Therefore, it is regarded as of minor importance from whose hands the supplementary powers may be supplied. While with a correct theory and general understanding by the lay mind, of the operative plan of medico-biologic science, as is now understood of the general plan of astronomic science, then no intelligent invalid would employ a physician who did not comprehend the working plan of the vital force energies.

In returning to the consideration of scientific principles it becomes evident that the condition expressed as an abnormal sensation constitutes the intervening situation always existing between the cause of disease and the development of disease as the first change experienced from the departure of health.

That ultimate life function expressed in the name of sensation is a department having many complex relations with the human organism, vastly more than can be considered at this time. Some sensations are recognized by the mind while many are not, that have direct relations with the involuntary department superintended by instinct. Keeping in mind that the involuntary department is set into special activity in response to a sensation, and not from an active principle introduced from without, it may be understood that the cause of disease does not attack the organism, and that all causes including microbes and germs are passive and merely cause abnormal sensations, that condition necessary for the presentation of involuntary pathologic activities; thus there is no warring of forces from without with the forces within.

When considering the relation of causes we should also recognize that while many causes are introduced from without, there is a larger number developed within. And we should observe a distinction between primary and secondary causes. The former may occasion a disturbance which, in itself, later develops a great variety of secondary causes for the continuance of disease. Such causes may exist as pathologic fluids which may undergo chemic changes having most virulent relations, together with congestions producing abnormal sensations of various kinds and degrees, with an increased temperature of the blood, often a dangerous cause, each being a secondary

cause for the perpetuation of pathologic activities.

The foregoing statements, when considered in association with the plan now taught, respecting operative medico-biologic science, may seem void of practical utility, but after the mind has grasped the correct interpretation implied in the separate functions of the four departments of ultimate active principles, it may then be recognized that this view of the situation is of exceeding great value in the management of disease. With medico-biologic science as well as with astronomic, it is important that we start right, that we recognize the correct operative plan, which will enable us to better understand the many details that are extremely practical to consider in persuading what we should do with the numerous variety of causes of disease, in other words, enabling us to better protect the patient from the relation of such causes. Some causes require to be neutralized by chemic changes which include the antiseptic, while other causes should be eliminated as early as possible. In many instances we should change the existing sensation, often completely swap sensations with medicinal contacts, and even abrogate sensations temporarily with opiates. And there can always be very much done to prevent the development of secondary causes within. It is often important to diminish the rapidity of production of the specific causes that develop as secondary causes with non-recurrent contagious disease, thus allowing elimination to keep up with the supply, and great success may attend the deploying of vital activity.

In the treatment of disease each of the several methods require consideration as to their applicability separately and jointly, a kind of thought exercise vastly superior to the treating of disease from a basis of experimental statistics. And there are two grand divisions of disease, one existing simply as abnormal sensation, and the other an associate disturbance existing as pathologic vital action. Both divisions may prevail separate from pathologic cellular construction, which constitutes malignant disease.

In summing up, we must keep in view the distinct functions of the four divisions of ultimate operative principles, how the cause of disease produces disease, the two divisions of causes existing as primary and secondary and protection of the organism by resort to different methods of treating causes existing in association with the two grand divisions of disease. Thus that higher education which is to contribute to a more successful treatment, and also protect invalidism from medical sharks, must be acquired through a better knowledge of the nature of vital forces expressed in special co-operative principles, that department of possible erudition which distinguished leaders allege must await the advent of future generations for its solution.

The authority quoted at the commencement of this paper suggested that we examine "the soil and that often what we consider the cause may be only the consequence of disease." Thus, respecting the soil, it is evident that micro-organisms will multiply rapidly wherever there is a food supply, and expire equally as rapidly when the supply is arrested. And the special food or soil favorable for this development in the human system is made to exist largely from pathologic vital action. Thus in the virus produced by non-recurrent contagious disease, the micro-organisms will multiply into millions and perish when the food supply or *materies morbi* is no longer elaborated. In

such instance the presence of the microbe becomes a consequence rather than a cause of the disease. And the reason why certain contagious disease is non-recurrent, is that the human organism can seldom develop such special virus but once in a lifetime, the *materies morbi* of such disease being a product from pathologic vital action and not a poison excreted or secreted by the microbe. The microbe does not come in and attack the human organism, but they simply multiply and consume the virus as scavengers. And in close association with such facts we are required to consider that complex problem represented in the term immunity. This problem, as well as the reason why certain contagious disease is non-recurrent, can not be explained from the present plan taught of operative medico-biologic science, while it is very easy of solution when considered from the correct plan of operative vital energies relative to existing causes of disease.

Scientifically considered, the immunizing principle is not operative except with non-recurrent contagious disease, while the temporary protection afforded with other forms of disease is not from immunity, but a protection from the deployment of pathologic vital activity. Whereas that protection experienced in the name of immunity, made possible with non-recurrent contagious disease is explainable as follows: With such form of disease a special morbid change prevails but once in a lifetime as the general fact, which pathologic act elaborates the virus of dangerous relations. And the danger attending such disease exists because such virus is produced more rapidly than it can be disposed of by elimination, thus becoming a secondary cause for complex disturbance. But when attenuated virus is introduced, a mild and incomplete pathologic disturbance will prevail, developing the special virus within the limit of safely possible elimination. And later, when pure virus becomes introduced, the previous partial change already effected has made it impossible for the organism to produce such virus rapidly in excess of elimination, as would be the fact had no previous mild disturbance been developed. Thus safety is practically insured because such pathologic disturbance has been effected on the installment plan. And with such disease the microbe or alleged germ develops rapidly from the abundant supply of food, but doing no harm to that organism which is the land of its birth, although such micro-organisms may become carriers of the poison, bottling up the special virus by their organization and giving it a longer existence. Such virus constitutes a secondary cause of disease in the organism where it is elaborated, and a primary cause when introduced within an organism that has never experienced such form of pathologic disturbance, while harmless to an organism that has previously experienced such disturbance. It is the virus, not the microbe, that becomes the cause of disease. The microbe or alleged germ may be a carrier of virus, while the virus of microbe construction is the real cause of disturbance. M. Pasteur states that the "virulency of the microbe depends on the quality of the material from which it is constructed." The microbe is not sufficiently complex in its organization to perform the function of excretion or secretion of poison, but does multiply and perish rapidly, to be succeeded by new births from the same material; and in the meantime the special pathologic virus may undergo chemic changes and become a more dangerous poison. Thus when we keep in mind the *modus*

operandi of how the cause of disease produces disease, we shall experience less fear of the microbe family and have less to say of disease germs. It is only the micro-organism that have been developed from some virus cause of disease that occasion pathologic disturbance to be manifested.

The cause of disease does not attack the living human organism. It does not act. The machinery of disturbance is operated wholly by the vital force. The cause is passive and only occasions abnormal sensations by its contact, generally expressed as irritability, in response to which pathologic vital action is developed, which in itself constitutes active disease. The superior success in modern surgery, alleged to be due to the killing of micro-organisms, may be better explained through the fact that the microbe-killer has changed the elaborated synthetic organic fluids, harmless as such, but which may soon enter into chemic changes in their downward career, producing poisonous products of dangerous relations existing as causes of disease developed within. Yet while the result of such practice has been construed in support of the germ theory of cause, the other explanation of protection is equally as well supported and certainly in better accord with the correct plan of operative life functions.

There is no army of disease microbes hovering in the air awaiting opportunity to attack exposed tissues, and the phrase "disease germ" is a misnomer failing to represent the correct situation of complex associations. The term is destined to become eliminated, being without usefulness in explanation of medico-biologic problems. Some forty years ago distinguished surgeons discovered that in operations, were the flaps allowed to remain exposed to the air until the oozing had ceased and the surface became glazed over, great advantage was insured to the individual.

And there is another discovery to be made of significant importance, implied in the fact that there is a vast amount of alleged medical science education inculcated that fails to develop scientific intelligence adding confusion in place of illumination to the vision of mental perception.

In closing I will call attention to another special feature of the situation, to be critically considered within the department of medico-biologic science, in the fact that ancient men made a serious mistake of interpretation respecting the operative plan, equally as fallacious scientifically as that perpetrated and long accepted by the early astronomer, as the Ptolemaic version. And this great error of dangerous infliction has been perpetuated unto our generation, and is now being thrust upon a defenceless people who are without thoughtful ability of escape, being assured through the influence of revered names that have become historic for presumed intellectual achievements, while such fame will be recorded in future history inglorious of scientific merit, and on a level with that of the early astronomers who failed to think in accordance with nature's methods regarding the operative universe. And among the numerous inflictions that have been thrust upon a civilized people from such error, may be recognized the misery which comes from a belief in the doctrine that alcoholic spirit may supply an "active principle" from without, as a supplementary power that will assist vital strength as remedial of weariness and debility. And no doubt there are many learned men who are so well satisfied with the present pseudo-scientific education, and so persistent that new

facts must be weighed by old methods, so over-persuaded by their early convictions, as to not care to give time for the comparison of this modern interpretation with the life phenomena presented. Yet it will ever remain a fact, not possible of supported contradiction, that medico-biologic science is based on the ultimate vital functions, normal and abnormal, of the four mentioned divisions of operative life principles.

THE ALLOXUR BODIES AND THEIR ESTIMATION.

BY H. RICHARDSON, M.D.,

CLINICAL PATHOLOGIST, MOUNT HOPE RETREAT, MD.

The alloxur bases have recently excited considerable interest among pathologists, partly on account of the difficulties of their direct estimation, but principally from the failure of exact analysis to confirm the "uric acid diathesis" theory.

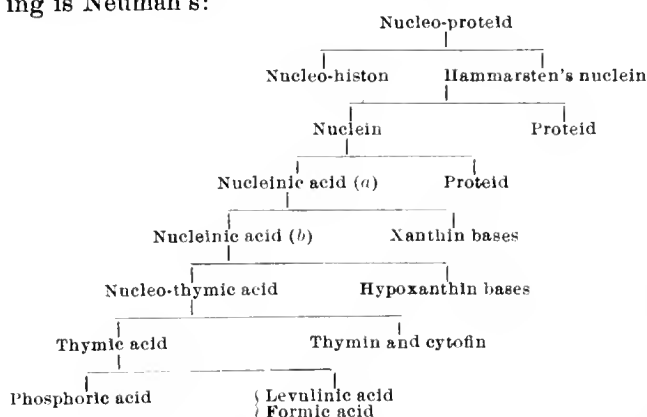

The latter theory dates from Garrod's discovery of an excess of uric acid in the blood in true gout, to culminate in Haig's teachings, who sees no difference between true gout, articular rheumatism, epilepsy, the "rut" of the springtime, religious excess and masturbation. He bases his theories on the formation of uric acid in the kidney, in a proportion of 1 to 33 of urea, when, owing to not very clearly defined conditions, a portion of the uric acid fails to be eliminated and is carried into the general circulation, to be deposited in the system, causing all sorts of ills when it is brought again into the circulation. Horbacewsky has proved that uric acid and the alloxur bases are formed from nuclein, and therefore we should expect, and we find, an increase of uric acid in leucocystosis, or any wasting disease, where there is excessive cell destruction. Haig's method of estimation of uric acid, viz., Haycraft's, is admittedly inaccurate, and further he administered salicylic acid or the salicylates to eliminate the uric acid. Boden has pointed out that the salicylates produce a leucocytosis, and in some very careful experiments shows that the elimination of uric acid runs parallel with the number of leucocytes.

Roberts, in his very elaborate investigations, finds that the uric acid exists in solution in the blood as a quadriurate ($C_5H_2N_4O_3HMC_5H_2N_4O_3H_2$), and that in the presence of an alkali the biurate is formed ($M_2C_5H_2N_4O_3$), which is barely soluble. This explanation accounts for the comparative failure of the alkaline treatment in gout and the insolubility of the tophi. He accounts for the precipitation of the uric acid in the joints, by the analysis of the synovial fluids, which he claims are the most alkaline secretions in the system. If the biurate comes in contact with a weak free acid or an acid salt, it is converted into the quadriurate and dissolved in the blood. Acid sodium phosphate (NaH_2PO_4) is the one used by nature and clinical experience partly goes to show that it acts as an eliminate of uric acid, besides in some cases reducing the tophi.

There are three ways to account for the excess of uric acid in the system: Imperfect excretion, increased formation, and both combined. In the early stages of gout, pathologists have failed to find any kidney lesion, and as other substances are eliminated in normal quantity, if kidney insufficiency was the cause, it would point to a special cell in the tubules, whose duty it is to eliminate uric acid, which presupposes an exactness of method not usual in the economies of

nature. It follows, therefore, that we must look to an increased production, and as in gout there is no leucocytosis and no pus, an excess of cell destruction, usually described as of nervous origin, is the conclusion by exclusion; added to this gout is usually associated with digestive disturbances pointing to defect in nutrition as the primary cause.

In the so-called gouty diathesis or uric acid diathesis, the clinical symptoms are so numerous that it has become a haven of refuge for the perplexed diagnostician. Careful analyses have shown that the elimination or non-elimination of uric acid bears no constant relation to the symptoms; it has therefore become necessary to look elsewhere. At present we are prepared to inculcate the xanthin bases. There are twelve alloxur bases, mostly found in the vegetable as well as the animal kingdom. They are adenin ($C_5H_5N_5$), hypoxanthin ($C_5H_4N_4O$), guanin ($C_5H_5H_5O$), xanthin ($C_5H_4N_4O_2$), heteroxanthin ($C_6H_5N_4O_2$), paraxanthin ($C_7H_8N_4O_2$), episarkin ($C_4H_6N_3O$), carnin ($C_7H_8N_6O_3$), epiguanin ($C_{10}H_{12}N_5O_2$), and others which have not yet been investigated. There are several schemes given for their formation. The following is Neuman's:

Thymine and cytofin are two recently discovered bases, of which the reactions have not yet been published.

The total amount of alloxur bases eliminated in twenty-four hours in the urine is very small, varying very considerably with diet. Camera found that with mixed diet the elimination was 87.0 mg., with flesh diet, 44.0 mg., with cabbage and apples 111.0 mg., with vegetable diet (peas and cabbage) 72.0 mg. He finds that the proportion of nitrogen in the xanthin bases to that of the uric acid is as one to 18.1, 7.6, 35.8, 18.1 respectively. Salkowski finds the proportion of uric acid to xanthin bases to be about 13 to 1; Flatow and Reitzenstein make the average quantity eliminated 29.2 mg.

Adenin ($C_5H_5N_5$), was discovered by Kossel in 1885 and is the simplest member of the group; it is apparently a polymerization of hydrocyanic acid. It is oxidized into hypoxanthin by the substitution of oxygen for an amido group. Lillienfeld, in his study of the chemistry of leucocytes, has shown that the nucleus of the cell contains a complex nucleohiston which is decomposed by acids into histon and leucocnuclein; the latter can in turn be decomposed into albumin and nucleinic acid, which, on heating with mineral acids, yields phosphoric acid and the nuclein bases. Adenin is best prepared from the mother liquor of tea. It does not appear to have any physiologic action. It has been found in the urine of leu-

kemia. Hypoxanthin, or sarkin ($C_5H_4N_4O$), is the oxidation product of adenin, from which it can be formed with nitrous acid. It is a normal constituent of human urine and has been found in excess in liver and kidney diseases by Thudichum, also in fevers and nervous diseases by Pouchet; according to von Jaksch it is present in exudates and transudates. Its physiologic action has been studied by Filhne, who states that 25 to 100 mg. begin to act on frogs in six to twenty-four hours, causing increased reflex excitability with convulsive attacks.

Guanin ($C_5H_5N_5O$) is principally made from guano. Von Jaksch states he has found it in transudates and exudates. Most observers have failed to find it in normal urine. Pouchet has found it in fever and nervous diseases.

Xanthin ($C_5H_4N_4O_2$) occurs rarely as calculi, more often as crystals in the urinary sediment. Normal urine is said to contain 0.032 to 0.025 grams in twenty-four hours. In the urine of leukemia, Stadthagen found an average of 0.07 gm. In tabes dorsalis, Pouchet found 0.08. The physiologic action is said to be a muscular rigor and paralysis of the spinal cord; the heart muscle is also affected.

Paraxanthin ($C_7H_8N_4O_2$), or dimethylxanthin, occurs in very small quantities in normal urine, it being only capable of detection in five to six liters. Rachford has found that it exists in excess in cases of migraine, and in epilepsy which is accompanied or preceded by migraine. He has not been able to find it in other forms of epilepsy. It is probably the most toxic of all the xanthin bodies yet studied, 1 to 2 mg. producing almost at once a rigor mortis-like condition of the muscles injected, with diminished reflex excitability without previous increase. Six to eight milligrams introduced into the lymph-sac bring on gradual loss of voluntary motion as well as of reflex excitability. In mice the reflexes are increased almost to a tetanus. The injection of 0.2 gm. in a 500 gr. guinea-pig produced convulsions and death in half an hour. The action of xanthin, hypoxanthin and paraxanthin seems similar, differing in degree.

Carnin ($C_7H_8N_6O_3$) appears to have no physiologic action.

Gerontin ($C_5H_4N_4$) has not been investigated, but is said to effect the nerve centers and heart ganglia; 0.5 mg. will kill 10 grams of frog.

Spermin ($C_5H_{14}N_3$) (?) is said to be tonic in its action.

From our knowledge of these bases it seems as if they are hardly likely to be of any great importance in diagnosis. Paraxanthin and possibly xanthin are the only members of the group which up to the present have been definitely associated with a disease.

There are three methods by which the xanthin bases can be estimated as a whole, viz.: The methods of Camera, Krüger-Wolf and Salkowski. The first two are open to the objection that they do not estimate the xanthin bases directly, but by estimating the nitrogen of the alloxur bodies and deducting the nitrogen of the uric acid estimated by some other method, thus throwing the whole of the error on to the xanthin bases.

Camera's method is as follows: Take a given quantity of urine and add a solution of sodium hydrate containing about 1.0 and dilute the urine to 1010 or 1011 specific gravity. Take aliquot part of diluted urine, add 5 c.c. Salkowski's magnesia mixture, filter; take aliquot part of filtrate, add 0.5 calcium carbonate and 5

c.c. of 3 per cent. solution of silver nitrate, allow to stand about two hours, filter; wash free from chlorin and silver, dry over sulphuric acid and estimate the nitrogen by Kjeldahl method.

Camera's modified method is somewhat more simple: Take 240 c.c. of urine, add 30 c.c. Ludwig's magnesia mixture and 30 c.c. 20 per cent. ammonia; shake well and filter; take 125 c.c. of filtrate (equal to 100 c.c. urine), add 10 c.c. of 3 per cent. ammonia silver nitrate solution, filter, wash and estimate nitrogen by Kjeldahl method.

Salkowski's magnesia mixture is made with magnesium sulphate 1 part; ammonium chlorid 1 part; ammonium hydrate, sp. gr. 0.924, 4 parts; water 8 parts.

Ludwig's magnesia mixture is made with magnesium chlorid, 100.0 grams, dissolved in water; add ammonia in excess and then ammonium hydrate until the precipitate is dissolved and fill up to 1000 c.c. with water.

The Krüger-Wolf method: Take 100 c.c. urine, boil, filter and add 10 c.c. of a 50 per cent. solution of sodium bisulphite, then 10 c.c. of a 13 per cent. solution of copper sulphate; after short boiling add 5 c.c. of a 10 per cent. solution of barium chlorid; remove from heat and allow to stand for two hours: filter, wash about five times with boiled water cooled to 60 degrees C., and estimate the nitrogen in the precipitate by the Kjeldahl method.

In all of the above methods the uric acid has to be estimated separately, the nitrogen calculated and deducted from the nitrogen found, the remainder being the nitrogen of the xanthin bases.

The usual method of estimating the uric acid is that of Hopkins of London, England. The writer uses the following modification: Take 100 c.c. of urine, acidulate with acetic acid, neutralize to slight alkalinity with ammonia and saturate with ammonium chlorid (about 30 grams is required); after standing three hours the precipitate is filtered, preferably with a suction-pump, the precipitate well washed with a saturated solution of ammonium chlorid, dried at 100 degrees C. to drive off any ammonia; then dissolve in distilled water, boil, cool, add 50 c.c. of a decinormal solution of hydrochloric acid, raise to the boiling point, cool and titrate the excess of acid with a decinormal soda solution, using dimethyl-amido-azo-benzol as indicator. The difference between the quantity of decinormal hydrochloric and soda solutions multiplied by 0.0168 will give the amount of uric acid, which divided by three will give the amount of nitrogen. As will be shown below, this method is not correct as some of the xanthin bases are partially precipitated by saturation with ammonium chlorid.

Salkowski's method recently published has the advantage over the above methods in that it estimates the xanthin bases directly: Take 600 c.c. of urine and add 200 c.c. of magnesia mixture, allow to stand one hour; filter; take 700 c.c. of the filtrate and add about 18 c.c. of a 3 per cent. solution of silver nitrate and allow to settle; if the precipitate appears granular or does not settle quickly add a little more ammonia, but as the xanthin silver salts are not perfectly insoluble in ammonia this requires care; take a specimen of the supernatant liquor and add nitric acid; if a precipitate takes place then the silver is sufficient. After standing one hour filter in a large filter and wash until on the addition of silver nitrate to the washings only a slight cloud is produced. The precipitate is suspended in water, a few drops hydrochloric acid added and the solution saturated with dihydrogen sulphid, warming

gently on the water-bath; filter and wash well; evaporate the filtrate to dryness, first on the flame and then on the water-bath. To the residue add 20 c.c. of a 3 per cent. solution of sulphuric acid (H_2SO_4 30 c.c., H_2O 900 c.c.), warm gently and allow to stand twelve to eighteen hours; filter; wash twice with the 3 per cent. sulphuric acid solution and once with water; add excess of ammonia and 1 or 2 c.c. of silver nitrate, testing as above as to quantity required; filter; wash well; dry, ash the filter in a porcelain crucible, dissolve the silver residue in nitric acid and estimate the silver by the Vohlhardt method.

Salkowski prefers estimating the silver instead of the nitrogen, on the ground that some ammonio-silver compounds are formed, which cause high results, on the other hand, adenin at least, and probably others of the xanthin bases form two silver salts which would tend to give high results by his method also. It is probable that by boiling the silver xanthin precipitate with magnesium oxid the ammonio-silver salt would be broken up and the ammonia set free.

The method is cumbersome, the filtration and washing of the large gelatinous precipitate, and the evaporation of a liter to dryness take considerable time. The author has substituted the following process, which gives the same results and is less troublesome:

It was necessary first to find out whether the whole of the uric acid was precipitated by the saturation with ammonium chlorid; to this end a sample of bought uric acid was purified by warming with 3 per cent. sulphuric acid, cooling, filtering and washing with water and then dissolving in a little potassium carbonate. Three portions of 100 c.c. each of the solution were each acidulated with acetic acid, neutralized with ammonia, saturated with ammonium chlorid, allowed to stand three hours, filtered, washed with a saturated solution of ammonium chlorid, the filtrate and washings made strongly alkaline with ammonia, 3 per cent. silver nitrate solution added, filtered, the precipitate washed, dried at 100 degrees C., and the nitrogen estimated by Kjeldahl's method; at the same time, to prevent error from possible nitrogen containing impurities in the reagents used, and from the ammonia in the atmosphere of the laboratory, a control test was carried through at the same time; four other tests were subsequently made under the same conditions with the following results:

	No. 1.	No. 2.	No. 3.	No. 4.
Nitrogen in filtrate found.	0.00014	0.00035	0.00042	0.00014
Nitrogen in control	0.00028	0.00028	0.00028	0.00007
Actual nitrogen in filtrate.	-0.00014	+0.00007	+0.00014	+0.00007
	No. 5.	No. 6.	No. 7.	
Nitrogen in filtrate found	0.00007	0.00042	0.00042	
Nitrogen in control	0.00007	0.00028	0.00028	
Actual nitrogen in filtrate	0.00000	+0.00014	+0.00014	

The average actual nitrogen found in the filtrate, after precipitation by saturation with NH_4Cl on the seven experiments was therefore 0.00006 or 0.18 mg. uric acid, showing that the whole of the uric acid was precipitated.

Being satisfied with this result, the following process was tested against the Hopkins and Salkowski methods: To 600 c.c. of urine add 200 c.c. of Salkowski's magnesia mixture; allow to stand one hour; filter; acidulate 700 c.c. of the filtrate with acetic acid; neutralize to faint alkalinity with ammonia, and saturate with ammonium chlorid (about 150 grams are required); allow to stand three hours: filter and wash with saturated ammonium chlorid solution. Warm the precipitate in a porcelain dish with 3 per

cent. sulphuric acid and allow to stand twelve to eighteen hours; filter; wash twice with 3 per cent. sulphuric acid and once with water. The filtrate including washings should not exceed 50 c.c. (3 per cent. H_2SO_4 dissolves uric acid in the proportion of 1 to 20,000). The filtrate containing the xanthin bases is added to the first filtrate, the mixture made strongly alkaline with ammonia, 3 per cent. silver nitrate solution added, filtered, washed and either the nitrogen estimated by Kjeldahl's method or the filter incinerated, the silver dissolved in nitric acid and estimated by the Vohlhardt method.

As some of the xanthin bases are precipitated by saturation with ammonium chlorid, in the following estimation the solution of xanthin in 3 per cent. H_2SO_4 solution and the filtrate from the saturation were estimated separately.

Hopkin's method.	No. 1.	No. 2.	No. 3.	No. 4.
Uric acid nitrogen	0.05208%	0.04032%	0.03528%	0.03268%
Xanthin nitrogen in filtrate from ammonium chlorid solution	0.00238%	0.00112%	0.00294%	0.00182%
Sulkowski's method.				
Nitrogen of xanthin bases	0.00325%	0.00284%	0.00267%	0.00346%
Author's method.				
Xanthin nitrogen in saturation filtrate	0.0026%	0.0018%	0.00226%	0.00173%
Xanthin nitrogen in H_2SO_4 filtrate	0.00108%	0.0016%	0.0008%	0.00093%
Total xanthin nitrogen, 0.00368%	0.0034%	0.00306%	0.00266%	0.00266%

It will be seen from the above four analyses made from urine that the methods employed give practically the same results, the average difference being 0.000536. The first three were mixed urines; No. 4 was a normal urine and it will be noticed that the proportion of xanthin base nitrogen to uric acid nitrogen is higher in No. 4 than in the pathologic mixed urines.

The author claims that his method is more simple and occupies less time than Sulkowski's, while giving practically the same results. Owing to laboratory difficulties the estimations of the nitrogen were made by Kjeldahl's method, a control being run through at the same time, and not by estimation of the silver.

Some experiments made some months ago led to the conclusion that xanthin was precipitated by saturation with ammonium chlorid out of an alkalin solution; whether completely was not discovered. Allen of Sheffield, England, states that it is probably almost completely precipitated under the above conditions. An attempt was made to settle the point by the following experiments.

A solution was made from some bought crystal xanthin, containing by calculation, 0.0033 nitrogen per 100 c.c. The solution was acidified with acetic acid, made slightly alkaline with ammonia and saturated with ammonium chlorid, allowed to stand three hours, filtered and washed with saturated solution ammonium chlorid. The precipitate was then warmed with 3 per cent. sulphuric acid and allowed to stand eighteen hours, filtered, washed and the filtrate precipitated with ammonio-silver nitrate solution, filtered, and the nitrogen estimated.

The filtrate from saturation with ammonium chlorid was also precipitated with the silver solution and the nitrogen estimated in the precipitate. The following results were obtained:

	No. 1.	No. 2.	No. 3.
Nitrogen of xanthin not precipitated by NH_4Cl	0.00168	0.00191	0.00182
Nitrogen of xanthin precipitated by NH_4Cl	0.00126	0.00102	0.00096
	0.00295	0.00293	0.00278

The experiments show that xanthin is only partially precipitated by the method employed.

The author has made a considerable number of estimations of the xanthin bases, but has failed to find any relation between them and mental disease, their total quantity varying in proportion to the metabolism, appearing to be greatest in quantity when the uric acid is small and lowest when it is excessive. He has failed to verify Rachford's results in epilepsy as yet, but a typical case of migraine epilepsy has not presented itself. In two cases of tabes dorsalis the total xanthins were excessive. As stated above it seems doubtful whether the xanthins are of much pathologic importance, their presence in excess being, probably, evidence of a want of oxidation in the metabolism.

ON THE EXISTENCE OF EPIDEMIC CEREBRO-SPINAL MENINGITIS IN CHICAGO, WITH REPORT OF A CASE WITH AUTOPSY.

Read at the Meeting of the Chicago Society of Internal Medicine, June 23, 1898.

BY JAMES B. HERRICK, M.D.,
CHICAGO.

The object of this paper is to prove two facts, first that a genuine case of epidemic cerebro-spinal meningitis has occurred in Chicago, the proof resting on the clinical history and the autopsy, the latter showing the presence of the meninges of the diplococcus intracellularis meningitidis of Weichselbaum; second, that this case was not a sporadic one, but that many other cases have occurred, or in other words, that there is a mild epidemic of cerebro-spinal meningitis in this city. So far as I can learn this is the first case of this disease reported for some time in this city and the first case in which the presence of the meningococcus has been recorded as found, thus establishing the nature of the disease beyond a doubt. That many other cases have been recognized as epidemic cerebro-spinal meningitis, I am well aware from conversation with physicians.

The patient was a male of 40 years, who on Friday, June 10, 1898, had a severe headache and backache. About this time he vomited. Tuesday, June 14, he came under my care in the Presbyterian Hospital. There was severe frontal and occipital headache, causing sleeplessness, and only relieved by morphin. The neck was rigid, and painful on attempted motion; there was but slight retraction of the neck. There was no paralysis nor any sensory disturbance aside from the pain already mentioned. The examination of the chest was negative. Over the skin of the abdomen and the thighs were very many light purple or violet petechial spots, but a few of them being larger than the head of a pin. The spleen was not palpable. The urine showed neither albumin, sugar, nor casts. The mind was clear, but the patient was restless and constantly complaining of his head.

He lived until 10:45 P. M. Sunday, June 19, dying five days after entrance to the hospital and on the tenth day from the onset of symptoms.

During these five days he had a fever of a remittent type, varying from 100.6 degrees in the morning to 103 or 104 degrees in the afternoon, the records being axillary. There was no pre-agonal rise. The pulse at first was regular and relatively slow, often being found below 90 though the axillary temperature was as high as 103 degrees. During the last thirty-six hours the pulse became more rapid, averaging about

124. The bowels were moved by enemata. Several times he urinated involuntarily; once he had to be catheterized. He never vomited after admission to the hospital. He gradually became wildly delirious and at four on the afternoon of the day he died the nurse recorded a "spasm lasting about one quarter of a minute." On the morning of the 17th his respiration was rapid, forty per minute. Numerous moist râles were heard over both chests and a patch of dullness with broncho-vesicular breathing was made out in the left lower lobe, posteriorly. He coughed up a sero-purulent material. Just before death the respirations were for several hours between 70 and 80 to the minute. The petechial spots faded somewhat before death, no new ones appearing. There was no herpes. No paralysis was at any time made out. No foci of suppuration could be found.

The clinical diagnosis was acute epidemic cerebro-spinal meningitis, broncho-pneumonia.

The autopsy was made twenty-four hours after death, and I am indebted to Dr. Hektoen for the abstract of the protocol and for the cultures and stained specimens of the micrococcus which I exhibit.

Autopsy twenty-four hours postmortem, by Drs. Hektoen and Freeman. Anatomic diagnosis: Acute purulent leptomeningitis associated with the diplococcus intracellularis; bronchitis and hypostatic pneumonia; cloudy swelling of the solid organs.

Abstract of the protocol (No. 532): A well developed, well nourished thick-set man; pronounced lividity; brownish spots in skin over abdomen.

Scalp and skull normal; the entire cerebral leptomeninx is infiltrated with a thick, yellowish, purulent fluid which is especially marked about the posterior margins of the cerebellum. There are no miliary tubercles to be seen. The amount of cerebro-spinal fluid is small but the lateral ventricles contain quite a quantity of purulent fluid which in the horns becomes a thick, yellowish pus. The walls of the ventricles are soft. The ears, orbits, sphenoidal and frontal sinuses are normal. The nose could not be properly examined. There is exudate around the upper end of the spinal cord, but the spinal canal was not opened.

The liver and the kidneys show cloudy swelling; in the kidneys the glomeruli are prominent. The heart muscle is friable and flabby. In the left lung the bronchi contain muco-pus; the posterior parts of both lungs are congested and heavy; in the posterior part of the left lung are large areas in which the substance is solid, deep-red, and rather homogeneous on the cut surface. The other organs are normal.

The bacteriologic examination: The smears from the meningeal exudate show a minute coccus, occurring often as a diplococcus, and free as well as in the interior of polymorphonuclear leucocytes; this coccus has no capsule and destains by Gram's method. The exudate is very rich in leucocytes, many of which show evidences of disintegration; large, uninuclear cells also occur, but these are few.

Glycerin-agar and serum (Löffler) tubes inoculated with the meningeal exudate and the ventricular fluid show after twenty-four hours in the incubator a number of minute, dew-drop like colonies which (in the agar medium) have a pearly, translucent appearance; their outline is circular and well defined, the central parts brownish under the microscope; these colonies consist of cocci, in the form of heaps, pairs and fours; there are no chains; they are promptly decolorized by

Gram's method. One or two larger colonies in one tube of glycerin-agar and one of serum were found to be the staphylococcus aureus and looked on as due to contamination. Otherwise these cultures were pure.

Inoculation upon new tubes of agar and serum and also in bouillon gives rise to a quite rich, typical growth which corresponds in all essentials to the descriptions of the diplococcus intracellularis meningitidis by Councilman, Wright and Mallory except that in the glycerin-agar tubes a considerable diffuse growth in the form of a very delicate film developed as well as the typical colonies. The authors quoted lay much stress on the absence of any diffuse growth of the organisms obtained from the cases that form the basis of their extended study.

About 1.5 c.cm. of the ventricular fluid was inserted into the abdomen of a guinea pig; the animal seemed a little sick but is still alive and apparently not very ill forty-eight hours afterward.

From the heart's blood and from the lungs cultures show staphylococcus pyogenes albus and bacillus coli communis; the spleen, liver and kidneys contain the colon bacillus. The histologic study of the organs is not completed.

The acute onset with headache, backache and vomiting, the rigid neck, delirium, the pulse slow regardless of a high temperature, the absence of splenic tumor, the petechial rash, make a picture of meningitis wholly unlike the tuberculous form, unassociated with primary pus foci and clinically resembling the epidemic variety. The finding in the meningeal exudate of the organism first described in 1887 by Weichselbaum, and later especially in the last few years identified by many as the specific cause of epidemic meningitis, its absence from the viscera would seem to furnish conclusive evidence of the nature of this case and to prove the first proposition that a case of epidemic cerebro-spinal meningitis has occurred in Chicago and has been partially identified as such.

For the proof of the second proposition, that an epidemic of meningitis exists in Chicago, I shall advance the oral testimony of many physicians who have told me of cases of meningitis that have recovered, the recovery of a case of meningitis being one of the strongest proofs that the disease is not due to the tubercle bacillus or to the ordinary pyogenic organisms, but to the diplococcus intracellularis. And I shall also give the abstracts of the following cases of meningitis seen by myself since Jan. 1, 1898, to show that an unusual number of cases answering to the epidemic form have been met with, in two of these there being recovery:

Case 1.—Child, 2½ years, seen with Dr. A. C. Cotton, Jan. 17, 1898. Headache, fever, vomiting and symptoms suggesting tuberculous meningitis. Remission in symptoms. Later, return with coma and death. Whole duration of illness about three weeks.

Diagnosis: Meningitis, either tuberculous or the mild remittent type of the epidemic form.

Case 2.—Adult, male. Convalescent from croupous pneumonia. Meta-pneumonic inflammation of right ankle joint and of neighboring tissues. Gradual improvement. Suddenly developing headache, vomiting, delirium, retraction of neck, fever. Death in twenty-four hours. Diagnosis, probable meta-pneumonic meningitis.

Case 3.—Seen with Dr. E. E. Prescott, March 13, 1898. Boy, 5 years, acute, excruciating headache, child beating head and pulling hair on account of pain, marked rigidity and retraction of neck, pain on moving neck or back, temperature 104 degrees, pulse very variable. Passed from my observation but I was later informed that a period of marked improvement and a pyrexia was followed by a return of headache, fever, etc., but that finally after about four weeks the boy seemed quite

well. Six weeks after the onset he was still in good health. Original diagnosis was a typical tuberculous meningitis. Without doubt this was a case of epidemic cerebro spinal meningitis.

Case 4.—Child of 3 years visiting in Chicago from Boston. Poor appetite, slight fever, cross for a few days. When seen March 20, 1898, quite dull and drowsy. Temperature 100 degrees. Two days later slight improvement. Then low fever from 99 to 102 degrees. Stupor, Cheyne Stokes respiration, abducens paralysis, unequal pupils, muscular twitchings and rigidity and death.

Diagnosis: Tuberculous meningitis.

Case 5.—Female child 2½ years, seen with Dr. Becker, March 24, 1898. A few days before, headache, vomiting, rapid respiration, high temperature. When seen in consultation comatose, no paralysis, rapid respiration, consolidation of upper lobe of lung. Death same day.

Diagnosis: Pneumococcus, cerebro-spinal meningitis though possibly of epidemic form with secondary pneumonia.

Case 6.—Adult male with old endocarditis producing aortic regurgitation. Cerebral embolism with right hemiplegia and aphasia. After being in hospital several weeks convulsions oft repeated, temperature, conjugate deviation of eye, coma, death.

Autopsy: Aortic regurgitation, old cerebral embolism with secondary softening, acute meningitis with purulent exudate; no primary pus focus. Failure to obtain cultures.

Diagnosis: Probable epidemic cerebro-spinal meningitis.

Case 7.—Seen with Dr. S. A. Hemmi, March 8, 1898. Child of 2 years in coma. Moderate temperature, early history indefinite, but suggestive of tuberculous meningitis. Two other children previously dead of brain trouble. Death.

Diagnosis: Tuberculous meningitis.

Case 8.—Seen with Dr. T. A. Davis May 1, 1898. Male of about 20 years. Onset with headache, pain in back and abdomen and vomiting, suggesting at one time appendicitis. Later excruciating headache, rigid neck, edematous and reddened area on dorsum of left hand (culture from this negative). Remittent temperature with much irregularity, pulse variable. Remission in symptoms, then return, with opisthotonos, delirium, rapid pulse; death after about four weeks.

Final diagnosis: Epidemic cerebro-spinal meningitis.

Case 9.—Seen with Dr. C. E. Sharpe, May 7, 1898. Male about 22 years. Felt rather poorly on retiring May 5, but went to work next morning, May 6. Left work on account of pain in back and head. Saw doctor at office; temperature 102 degrees. Ate supper; in night vomited, headache severe, grew stupid. When seen in morning was comatose and hemiplegic, temperature 103 degrees, pulse rapid and weak, involuntary discharges. Later history not obtained as yet.

Diagnosis: Epidemic cerebro-spinal meningitis of fulminating type.

Case 10.—Child of 4 years seen with Dr. DeBey June 9, 1898.

Child taken suddenly four weeks before with vomiting, headache, delirium, retraction of neck, convulsions. Diagnosed by doctor as meningitis. Fever lasted about ten days; had disappeared when I saw the child. There was no complaint of pain, no rigidity of neck, but complete deafness. Child extremely cross and irritable. Great emaciation. To-day, June 23, Dr. DeBey reports condition as practically the same, though emaciation and weakness are more pronounced.

Diagnosis: Epidemic cerebro-spinal meningitis.

Case 11.—Case just reported with diagnosis proven as epidemic cerebro spinal meningitis.

Case 12.—Adult male entered Presbyterian Hospital June 22 with diagnosis of typhoid fever with meningeal complication. From intelligent patient and from wife learned that onset was rather sudden two weeks ago with chill, intense headache and vomiting. Two nights later was delirious, as well as the day following. Temperature said by doctor to have been 104 degrees. No good sleep for these two weeks on account of severe headache, though other symptoms have improved. No spleen or other earmarks of typhoid. Temperature in evening 101 degrees.

Diagnosis: Possible mild case of cerebro-spinal meningitis.

Of these twelve cases, I believe two were tuberculous (4 and 7) in character, two were probably of pneumococcus origin (2 and 5). The diagnosis in case 1 may be questioned, though the phenomena are explained as well on the supposition of the epidemic form of meningitis as on any other. The case of the hemiplegia, case 6, was probably of the epidemic variety. The cases 8 and 9 are excellent examples,

the one of the subacute form with remissions, the other of the fulminant variety. Case 12 is a possible mild subacute case. The cases that recovered, cases 3 and 10, were certainly cases of meningitis; their history is typical of the epidemic and their recovery an almost positive proof that such was their character. In case 11 the proof is conclusive. In other words, of twelve cases of meningitis seen, one is proven of the epidemic variety by bacteriologic examination; two by the clinical history and fact of recovery; two by the clinical history and exclusion of other forms; three are probably of the epidemic variety, though this diagnosis might be questioned; two were probably tuberculous; two probably pneumococcal.

That my experience in meeting with an unusual number of cases of meningitis is not unique is shown by the fact that there is current comment among physicians on the frequency of meningitis in Chicago, and that not a few cases recover. And in other parts of the country cases are reported. Boston has had an epidemic that has furnished the basis for Councilman's report with 35 autopsies. Baltimore is furnishing its quota to the wards of Johns Hopkins Hospital; the army surgeons are meeting with cases among the soldiers. A physician practicing in a country town in Iowa told me three days ago that he had seen six cases of meningitis in about three months and that some had recovered.

This being the fact we can be more guarded in our diagnosis and prognosis in our cases of meningitis. And we should, when in doubt, put our diagnosis on a surer basis by attempting to obtain the organism by lumbar puncture, a procedure regarded as without danger in this class of cases and as furnishing us in the majority of instances, when done early, with a sure means of determining the etiologic factor in the case, which knowledge influences materially the prognosis, and it is to be hoped, at some near day, the treatment.

SOCIETY PROCEEDINGS.

Associated Health Authorities of Pennsylvania.

Fifth Annual Meeting held at Lancaster, Pa.,

May 18 and 19, 1898.

(Concluded from page 1522.)

SECOND DAY.

The report of the Executive Committee by Dr. Lee, detailed the doings of that committee to provide for this meeting, the change of time and the arrangement to a visit of inspection to the Vaccine Farm at Marietta conducted by Dr. H. M. Alexander. It mentioned the almost total want of attention to the meetings by the local boards of health, their unwillingness to subscribe to the funds, and the need of money to pay the indebtedness to Dr. W. B. Atkinson for publishing *Public Health* and the issue of a circular appealing to all to aid the Association by contributing yearly. Also it alluded to the success of the New Jersey State Sanitary Association and the Maryland Public Health Association, and presented the Constitution of the latter as an idea of how to obtain members in the want of better interest on the part of the local boards.

After some discussion on motion a committee was appointed to report to this session some plan of amendment of the laws of the Association by which to add to the membership, etc.

The Committee on Legislation reported efforts to obtain legislation by the State Legislature for several sanitary matters, all of which had failed owing to the want of money in the State treasury from the burning of the State capitol.

The Committee on Publication reported as to the need of money to continue the work of the Association, and the great desire on the part of all to keep the publication of the Journal from lapsing. Not 10 per cent. of the local boards had joined the Association, mainly owing to the lack of funds, as the vil-

large councils refused to vote them funds for any purpose. The committee commended the work done by the Journal and the courtesy of the editor in performing the work without hope of compensation.

Dr. D. H. BERGEY, first assistant in the laboratory of hygiene, University of Pennsylvania, read a paper entitled:

POLLUTED WATER SUPPLIES; THE NECESSITY FOR LEGISLATIVE RESTRICTION OF THE POLLUTION OF SURFACE WATERS THROUGH THE SEWAGE OF TOWNS AND BOROUGHS DRAINING INTO PONDS AND STREAMS THAT SERVE AS SOURCES OF WATER SUPPLIES FOR OTHER TOWNS AND BOROUGHS.

He said the frequent complaints made to the State Board of Health, of polluted water supplies and the almost invariable verification of the truth of such complaints by careful analyses of such waters, make it necessary for the State at large to devise means for abating these nuisances in an effective manner. The water supplies of many towns and cities are grossly polluted at the present time. Perhaps the most notable example of this pollution, not only of the State but the whole country, is that of Philadelphia. There are many other cities and towns in the State whose water supplies are grossly polluted to such an extent that they are unfit for use as water supplies without previous purification of the water. Wherever the water supply of a town is derived from these streams, filtration of the water is necessary in order to protect the health of the community against water borne diseases. The necessity for legislative restriction of the pollution of surface waters does not rest, primarily at least, upon the fact that pollution of these waters will require their filtration to render them fit for domestic use. Such legislative restriction is called for more particularly from the fact that some of these streams are now, or were rapidly becoming, direct menaces to the public health of the communities through which they flow. It is no longer to be expected that these surface waters can be maintained in such a condition of purity as to serve as sources of water supplies without previous purification of the water. The drainage areas of most of the water courses are already so thickly populated as to render this out of the question, so that aside from the drainage of towns and boroughs along their course, there is sufficient polluted material gaining entrance thereto from the thickly settled rural districts to continue to render the water unfit for domestic use unless purified. In order, therefore, to prevent these water courses from becoming direct menaces to the health of the communities through which they flow, it is necessary to restrict the pollution through sewage that is now taking place. The only way, it seems to me, that this can be accomplished is through the enactment of laws prohibiting such pollution. Such laws should prohibit the entrance of all new sewers into any water-course which, in any part of its course, serves as a source of water supply for another town. This law should also demand that whenever practicable the drainage of towns now draining into these towns shall be subjected to some reliable method of purification in order to render it innocuous before entering the streams. In order to lessen the expense and to render the purification of sewage more efficient, it is suggested that a number of towns be combined together into a single drainage area and erect a single purification plant for the entire area. Attention is also called to the objectionable character of manufacturing waste and the signal manner in which it increases the pollution of streams. So far, the States that have secured important legislation restricting the further pollution of streams, somewhat along the lines of the Rivers Pollution Act of England of 1876, are Massachusetts, New York and West Virginia. So far legislation in our own State has not been secured to this end, though several bills have been introduced into the State legislature since 1891 tending to bring this about. It is urgently demanded that such legislation be secured in Pennsylvania, on the strength of the knowledge already obtained with regard to the grossly polluted condition of our several streams.

Dr. Bergey's paper was discussed by many of the members, and on motion, the acts offered in 1891 and 1895 were again referred to the Committee on Legislation and they were instructed to urge their adoption by the legislature at the coming session of that body.

After allusion to the lecture of Professor Rothrock, the following was unanimously adopted:

WHEREAS, The Associated Health Authorities of Pennsylvania have already placed upon record their opinion that the best interests of the commonwealth would be subserved if the State should become the possessor of extensive areas at the head waters of our principal streams, and

WHEREAS, Up to this time no direct action has been taken

to secure these lands which are so essential to the future of the Commonwealth; therefore, be it

Resolved, That we again place ourselves upon record as endorsing for this State a system of forestry reservations such as have proven to be of so much value to the health and commercial interests of the State of New York.

Dr. THOMAS TURNBULL, Assistant Bacteriologist of the State Board of Health, read a paper entitled

SUGGESTIONS FOR LEGISLATION IN THE INTERESTS OF A MORE COMPLETE SYSTEM OF SANITARY ORGANIZATION OF THE STATE.

He referred to the menace to cities and towns throughout the country districts, in the absence of any form of health authorities, all who were suffering from any form of contagious diseases were not prevented from being at large and thus constantly distributing the infection to others. He quoted the common belief that measles, whooping cough, even scarlet fever, were regarded by the people as not of import, hence the objection to report them and often the non need of any medical attendance. Thus these contagions were being carried everywhere, and thus were epidemics kept up. It was a prime necessity that such legislation should be enacted that would prevent this which was an outrage upon the people. He also alluded to the necessity for a codification of the existing health laws of the State, and quoted the admirable system now existing in the State of New York, which he held up as a model for Pennsylvania.

Dr. B. LEE read a paper on

TRANSPORTATION OF THE DEAD.

He said this is not a safe thing to do unless under certain restrictions. A physician's permit is not sufficient, boards of health alone should give the permission, and these only after very careful consideration. It is not a question of proper respect for the dead, but of health for the living. In our affection for the dead we are apt to forget the other and sanitary side. The danger is greatest in the country, where there is no supervision, but there the hold is to be had in the transportation companies, who are coming to understand the risk to the health of their employees and the trouble the law will give them. Diphtheria, he thought might be placed upon the free list of not absolutely contagious diseases, the use of formaldehyde doing away with the danger. The examination and registry of the embalmers and the responsibilities of undertakers were touched upon, the certainty that those who prepare the bodies understand their business being essential. The opposition by the members to the placing of diphtheria on the free list was very emphatic among those who discussed the matter, but Dr. Lee believed that if it could be done, if the concession could be safely made, it ought to be done.

CROSBY GRAY of Pittsburgh thought in place of lessening the list, scarlet fever and measles should be added to it.

Dr. M. L. DAVIS of Lancaster then addressed the Association upon

THE DISPOSAL OF GARBAGE.

illustrating his remarks by pictures on the screen. He said: We would feel like apologizing to you for referring to the importance and necessity of the sanitary disposal of garbage were it not a fact that in the closing days of the nineteenth century the great majority of the centers of population are without any means or system for this purpose other than to remove it from the most objectionable place in or near the buildings to one a little less undesirable because more out of the way. The great State of Pennsylvania, with its 6,000,000 inhabitants, has forty-nine cities having more than 10,000 people; and in only eight of these forty-nine cities have any other means been adopted for the disposition of garbage than by dumping it at some unfrequented place. The practice for many decades has been for inland cities to convey their garbage to a dumping-place, while seaport cities loaded it on scows, which by the terms of contract were to be towed ten miles out to sea and the cargo then thrown overboard; this we presume, was sometimes carried out, but we know to a certainty that New York Harbor as well as Delaware Bay has been the depositing place for many a barge load. Philadelphia, until within the last five years, has emptied all of its sewage and much of its garbage into the Delaware and Schuylkill Rivers; the solid portions have deposited upon the bottom of the channel until it became too shallow for large vessels to enter the port, and we now witness the interesting spectacle of the United States Government expending millions of dollars to remove the filth which Philadelphia dumped in front of her own door.

Philadelphia, by this irrational and unwise action, had cut off the possibility of large vessels entering her port, thereby losing valuable shipping trade. Inland cities are doing just as irrational a thing, but in a different direction. They deposit their garbage in some old abandoned stone quarry, an abandoned

sand pit or "sink hole," there to decay and poison the air by the fumes arising from its decomposition, and the water-supply when well water is used by the filthy material carried into the ground by rain, finally finding its way into the wells.

It is interesting to note how the cities of America dispose of their garbage; an investigation some time since by Mr. Randolph Hering of New York into the methods employed by 150 American cities, elicited the following: Forty-six cities disposed of it by filling or plowing into the land; 14 by dumping it into the sea, lakes or large rivers; 43 cities employed it to feed animals; 17 employed reduction plants, recovering the grease for soap-making and making the residue into fertilizers; 30 disposed of it by burning in various kinds of garbage furnaces. Thus, while 103 of the cities investigated disposed of their garbage in dangerous and improper ways, only 47 adopted safe methods. It is only of late years that any scientific method of garbage-disposal has even been sought for.

The rapid advancement of sanitation, the establishment of boards of health in cities, enforcing greater cleanliness, made a demand for a better method of disposing of this dangerous refuse and nidus of disease-breeding germs. The law of demand and supply came to our relief. The inventor's mind was turned to the subject and as the substance to be destroyed was impure, naturally the only sure purifier in nature, heat, was suggested. Various methods were devised to apply the heat in the best possible manner to burn the material to be disposed of.

It is our desire to explain to you how this can be accomplished in the cheapest and most cleanly manner, by considering the various methods of disposal plants and their systems of operation.

Garbage, in this sense, should be confined to kitchen waste, that is, the rinds of oranges, bananas, apples, peaches, water-melons, cantaloupes, waste scraps of bread, etc., and the many things of an offensive nature that accumulate in a kitchen and about a house, which are capable of undergoing putrefaction or carrying the germs of disease; the refuse of market stalls and the establishments for sale of fish, fruit and vegetables. Other substances should never be placed with garbage, as they either require separation from the garbage in some processes, or in others take the place of an equivalent amount of destructible material, and thereby encumber the economic destruction of the garbage proper.

In referring to the decomposition of garbage as being dangerous, we do not wish to be understood as advocating the theory of some that disease germs are produced by such decomposition, as we firmly believe that the particular germ of every disease which afflicts the animal body is placed in or received into that body in an embryonic state, to be developed, and to the processes of development and reproduction of its kind are due the manifestations of the disease to which the germ belongs. For example, in typhoid fever the germ enters the alimentary canal, the eggs lodge in Peyer's glands and there develop, and it is the irritation produced by this growth which causes the symptoms of the disease. That the decomposition of garbage or the decomposition of any other substance will produce these germs we do not believe; but filth of any kind, and putrescible filth especially, furnishes an excellent nidus for such germs, and no better material for their collection and preservation can be found.

The amount of garbage produced by different cities varies very much, dependent largely upon location, modes of living, employment, etc. American cities, owing probably to more lavish modes of living, produce much more garbage than European cities of the same size. Cities located as those along our Jersey coast, where transportation facilities are such that one or two hours' time will deliver at their doors any products from Philadelphia and New York, this, and the class of people who frequent such resorts, cause large quantities of perishable vegetables and fruits to be used, hence a very much greater amount of garbage will be produced than in inland cities of the same size.

The average daily amount of garbage produced by American cities is one half to one ton for each 1000 population. This can be taken as a safe basis to calculate from, as only in rare instances will it fall below or rise above this amount.

The following tabulated amounts of garbage collected from the cities named prove the correctness of this estimate:

Buffalo...	per capita, 0.245 pounds per day.
Boston...	per capita, 0.946 pounds per day.
Wilmington...	per capita, 0.805 pounds per day.
St. Louis...	per capita, 0.277 pounds per day.
New Bedford...	per capita, 0.890 pounds per day.
Cincinnati...	per capita, 0.566 pounds per day.
Philadelphia...	per capita, 0.832 pounds per day.
Lowell...	per capita, 0.408 pounds per day.

Two methods of disposing of garbage are being adopted at

the present time, to the exclusion of others; during the last five years all the cities which have abandoned their insanitary modes of disposal have adopted one or the other. The one process is known as the utilization process, and the other, by burning it in a furnace constructed particularly for the purpose, is misnamed the cremation process. We will consider first the utilization process. The idea that there was material in garbage which, if reclaimed, would be of value, was the incentive which developed this method of disposal, with a view to make a fortune out of the product. There are in use two kinds of utilization processes. In the one kind benzene or naphtha is used to dissolve the fat contained in the garbage. Among the principal ones of this kind are the Merz and the Pierce. The Preston, Halthaus and Arnold are purely mechanical processes, no chemicals being used. The machinery and appliances of both systems are practically the same, except in the one a naphtha tank. The special machinery consists of large iron tanks, fifteen feet high by five in diameter, provided at the top and bottom with means to be closed steam tight; they each hold seven tons of garbage, and upon their number depends the capacity of the plant. Presses to press out the grease, dryers to dry the solid portions, fume destroyers, grease-extracting tanks, naphtha tanks and condensers, screens, mills for grinding the coarse material after having been dried, together with boilers, engine and the many utensils required to operate a plant having so much machinery. The iron tanks which receive the garbage are called cooking tanks, extractors or digestors. As a description of one of these plants will suffice for most of them, we will describe the process the garbage goes through in such a plant. The garbage is conveyed to the reduction plant by carts, which are weighed upon scales; the cart then goes to the rear of the building, when it enters and dumps its load into a large pit, where two men stand in the foul mass and fork it into elevators, which convey it to the digestors; these men separate the tin cans and other substances found in the garbage. A visitor to a plant at Pittsburg describes the process thus from this pit: One line of these hoppers, the descending one, is empty. It turns upward and gathers up a great wad of the reeking refuse. Working like the belt of an engine, but slower, the hoppers carry their load up and come down empty. It is carried up to the third story. Round the rear of the building you come to a flight of stairs leading up to the second and thence to the third story. Here is where the process of reduction is begun. In the third floor room you realize that this place is less a garbage furnace than it is an odor-destroying institution. The process of cooking the refuse is simple and requires little, though awkward lumbering machinery. The devices for carrying off any objectionable smells and holding them from ascension into the air are numerous and complicated and occupy most of the space of the room. There are fans and pipes and ducts and furnaces. A single narrow building where the digestors might be stored would be sufficient to get rid of the garbage. A great square building with many attachments inside and out is necessary for the destruction of the odors.

When the hopper is filled and ascends to the ceiling of the third floor its load is emptied into a duct. Carriers bring it along the roof until it is over one of the huge digestors. These are huge cylindric vessels, probably fifteen feet high and five or six feet in diameter. Each of them is capable of holding seven tons of garbage. They are filled every four hours and are working night and day. The top of the digester is just under the duct that carries the material from the hoppers. This gives them some six feet on the third floor, while the under portion is upon the second floor and extends down to a vessel, technically known as the dryer.

The room in which the digestors are filled is as clean as an office. Attendants are kept busy about the big cylinders, as there are bits of garbage that can not be prevented from falling out when the hoppers empty their load. The boys have brooms, and as a bit of stuff falls on the floor it is swept up and put into the vessel. Every window of the room is open. Going to one of these windows you find it peculiar that there is only the draught of air inward. Not a breath goes outside. Yet the windows are open all about the room, and there are many windows. This is explained by the big fan and air-pipe. Coming from the air-pipe are numerous cylinders extending from the pipe about halfway to the floor. These end in a funnel-shaped spread, and a hand placed at their mouth finds the air sweeping up into them. It is absolutely impossible for a disagreeable odor to get outside the windows. The fan is capable of carrying away 75,000 cubic feet of air a minute.

But to go on with the garbage. The seven-ton digester is full. The steam-tight and air-tight doors at the top are closed after having admitted the stuff. There are similar doors at

the bottom of the digestors. They are so arranged that they can easily be opened and shut. The digester is supported on a huge iron frame, and the fact that simply opening the doors at the top fills them and opening at the bottom empties them shows the facility of the work. It can be worked at both ends in a moment. Any bad air that may emanate while this process is going on is well taken care of by the big fan. There are valves and pipes arranged so that the steam for cooking may be admitted into the cylinder.

In many of the garbage furnaces there is a step here in the reduction that is not taken in the Pittsburg establishment. It is the crushing. Perforated cylinders are sometimes filled with the cooked and charred stuff now called tankage instead of garbage, and an immense pressure is applied to it. This squeezes out much of the water and grease in the tankage. The grease is utilized and considerable income, about \$500 a day, would be derived from this grease here. An estimate places the amount of grease that can be obtained from 400 tons of garbage, at that figure. But it is not all grease that is derived from the pressing process. Much of it is foul, rank water. This is the reason the pressing is omitted. The drinking water of the city is obtained from the river, and were the tankage pressed the water would be drained off into the river. Where they have an ocean in which to empty the dirty liquid the pressing can be done advantageously. Instead of pressing the tankage, therefore, it goes immediately to the dryer. There any water or moisture that still remains is vaporized or absorbed. From the fourteen digestors of the factory the tons of garbage are reduced greatly, and seven dryers hold the tankage. Each dryer receives about four tons. The dryers are steam-jacketed cylinders in which huge arms are constantly moving about. They stir up the contents and submit every portion of it to the heat, so that it is thoroughly dried. The heat, which is applied through the cylinders, is the same in every part. The garbage in this process is much broken up and disintegrated.

It is from the dryers that much of the objectionable odor comes. In the process the water and grease of the tankage is bound to be converted into vapor. This is evident in the fact that after the digester and the dryer have finished with the garbage only about 20 per cent. of the stuff remains. There is 80 per cent. odor, and such a vaporization might, if allowed free access to the atmosphere, bring misery to many noses and cause the condemnation of many Christian souls. So, heroic measures are used on the dryers.

There is a vacuum-pump next the engine room in the rear of the building. It is a pretty and powerful little arrangement. There is a big cylinder, and the pump by constant suction establishes in the cylinder a vacuum. Attached to the dryer are pipes and ducts similar to those upon the third floor. These pipes connect with the vacuum-pump and immediately the vapors take form and make for the aerial quarters they are seized, drawn into the pipes and brought along by the vacuum. None of the vapors can escape. This is evident, inasmuch as there is not a particle of odor in the room with the dryers.

When the dryer has done its work with the tankage the work is over so far as the garbage plant is concerned. There are little carts under the dryers that have air-tight tops fitted on them. These carts are somewhat similar to those the street cleaners drag about, scarcely a deviation from the ordinary fruit vendor's push-cart. From the dryers the carts take the tankage back to the rear of the building, adjacent to the pit; just where it came from a few hours previous reeking, foul-smelling, filthy. The load that the cart has is again elevated. There is a sort of permanent crane upon which the tankage is hoisted. Freight cars are run under this crane and all that remains of the garbage is dumped into the cars, a charred mass.

Of the possibly 100 tons that went into the digester there are about twenty tons left to be converted into fertilizer. The tankage is crushed, ground up and chemically treated, and its end is first-class fertilizer.

There are three furnaces that are used to get rid of the vapors. Some of the fumes that come from the dryer are susceptible to condensation by a spray of cold water. The greater part of them, though, must be destroyed by heat. The vapors from the pipes are usually sent through a spray of cold water, and some of the gases taken away. The remainder goes into the incinerating furnace. There are three of these furnaces, all with huge boilers. Inside the cylinders, the pipes are coiled up until many feet of pipe are there. The gas flame is applied to these coils. It is a process similar to distillation. The vapors are run through these pipes and subjected to an intense heat. They lose their identity there in decomposition. They are separated and destroyed. At the side of the engine there are exhaust pipes. Opening the exhaust, steam and water are discharged. In a few moments the odor is percep-

tible, and it grows more intense all the time. It is highly disagreeable, resembling hydrogen sulphid, the most disgusting chemic compound known. The odor is somewhat like putrefied cabbage boiling. By placing a handkerchief at the exhaust the odors and vapors will condense upon it, and an idea obtained of the insurrection that would arise were the vapors turned on the air. But when the incinerating furnace has finished with the vapors there is absolutely no odor left. There is therefore none to ascend to the bluff above or to cause trouble. From the pit in the rear it is possible that some may ascend, but that is the only place, and the effect is inconsiderable. This is the odor that bluff residents occasionally smell. The huge fan at the top can cause a draught that sweeps the odors from all the floors. It is on the third floor, and its effect is felt on the first. From the digestors all odor goes into the pipes, and the same may be said of the dryers.

The outlay for the operation.—There are thirty wagons, each with a driver and a helper, and each with two horses. The driver gets \$1.66 $\frac{2}{3}$ a day, and the helper gets \$1.50. About the works on Second Avenue the forty-five men employed at various salaries are from office boy to superintendent. It is not unfair to place the wagon men at \$30,000 and the others at \$20,000. There is the sum of \$30,000 still to be used in the garbage furnace alone. Of the \$30,000 that remains, the horses must be kept, the factory must be kept up and incidental expenses must be borne. Incidentals cover a multitude of sins. But whatever else can be said of the garbage plant its efficiency can not be denied. It is visited by officials of other cities, and is called perfect.

To summarize, the utilization method is to receive the garbage in a pit, separate tin cans and other solid material from it, convey the garbage proper to the digestors, where it is treated by a cooking process by steam alone in the one case and in the other by steam and naphtha to extract the grease, the pressing out of the liquid, drying of the solid portion and grinding for fertilization, and the distillation of the naphtha to reclaim it.

The burning method of disposing of garbage is accomplished by two methods; the one utilizes the carbon in the garbage as fuel and the other does not. These furnaces are of the horizontal type; when the garbage is dumped through openings upon a grate a fire at the end furnishes the heat to dry and burn the garbage. A second fire in or near the stack destroys the odors from the burning garbage.

Let us consider the cost to the different cities using utilization or burning. Milwaukee pays \$1.48 per ton to have its garbage disposed of, St. Louis \$1.32 per ton, New York \$89,000 per year, Pittsburg \$80,000 per year; this does not embrace collection.

That the destruction of garbage is desirable by suitably built furnaces in the vast majority of cities is unquestionable.

The horizontal furnaces have burned of late, at Wilmington, 500 tons of garbage with ninety tons of coal, or 39.9 cents worth of fuel to destroy a ton of garbage. The Davis furnace has burnt forty tons of garbage with one ton of coal, or a record of 6 cents worth of coal for each ton of garbage; including the fireman's wages would only amount to, for a day's burning of forty tons, \$1.50 fireman and \$2.15 one ton of coal, or \$3.65 besides the interest of the plant. Whilst the reduction plants want for the same work \$52.80, besides the process of reduction is not only more expensive, but the separation of the offensive material is repugnant.

Before illustrating the different systems we would call your attention to the subject of the domestic disposal of garbage. There are many towns too small to use a garbage plant, but when the disposal of garbage is an important item we might show how this can be done in the ordinary stove or range.

The special committee reported an amendment to the laws allowing any one interested in sanitary matters to join the Association on payment of one dollar yearly, with all the rights of any members, and the addition to the name of the Association of the word sanitarians, making it "The Associated Health Authorities and Sanitarians of Pennsylvania." These amendments were unanimously adopted.

Dr. LEE offered a humorous resolution urging the removal of the constant menace of the filthy condition of Cuba by the proper administration of certain articles. After some discussion on the importance of such a matter a resolution was presented by Dr. Lee.

WHEREAS, In consequence of entire neglect of the Spanish authorities in the Island of Cuba to inaugurate and enforce such sanitary laws and regulations as exist in civilized countries, the diseases of smallpox, yellow fever and leprosy constantly prevail unchecked in that island, and

WHEREAS, In consequence of the proximity of Cuba to the United States and the intimate relations between the two countries, the condition referred to constitutes a constant men-

ace to the public health of this country, involving the most painful anxiety, considerable pecuniary loss, and in repeated instances serious loss of life, therefore

Resolved, That no settlement of the pending difficulties between the United States and Spain will be satisfactory to the sanitarians of this country which does not insure to the United States the absolute control of the sanitary administration of the Island of Cuba.

This was adopted by a unanimous vote.

The officers chosen were: Crosby Gray, Pittsburg, first vice president; Moritz G. Lippert, C. E., Phoenixville, second vice-president; J. B. Tweedle, Weatherly, third vice-president; Wm. B. Atkinson, Philadelphia, secretary; Jesse C. Green, D.D.S., West Chester, treasurer.

The Association adjourned to meet in 1899 at the call of the Executive Committee.

German Congress of Internal Medicine,

April 13, 1898.

The President in his address referred to the campaign against Vivisection, which has been revived in Germany, and mentioned as an instance of the non-antagonism between vivisection and love of animals, that the physiologist, C. Ludwig of Leipsic, is president of the Society for the Prevention of Cruelty to Animals. The first session was devoted to "Medical Education." A ten-semester course was advocated, with increased facilities for practical technical training in diagnostic methods, laboratory work and general therapeutic methods (dietetics, inhalations, hydro-, mechano-, electro-, balneo- and climatotherapeutics), with practical bedside courses. The internal clinic should be four semesters, ten hours a week. The folly of creating a special chair for any branch of internal medicine or therapeutics was emphasized. Leo announced, in his address on "Diabetes," that the new preparation by E. Büchner of crushed and compressed yeast, which while filtered free from cells still contains the zymosis, the sugar-splitting element, produces a remarkable curative effect on dogs rendered diabetic by being fed with a solution of sugar fermented with yeast until the sugar has vanished. The diabetes thus induced lasts several days, and produces great emaciation if long kept up. It demonstrates that the elimination of sugar in individuals after copious beer-drinking, is due to some toxic metabolic product of the yeast cells. Beer, therefore, should be avoided by persons inclined by heredity to diabetes or already affected. He urged periodic investigation of the urine and weight in diabetics by the physician, "not the druggist," to determine periodically the capacity for assimilation. The "Heat Production in Fever" was attributed by Krehl to the fever-producing substances in the circulation. An increased amount of organic albumin is decomposed, with the albumin molecule hydrolytically split. The albumoses thus formed, far advanced in hydration, enter the circulation and are eliminated through the kidneys. The products of this decomposition of the albumin affect the nervous system as a toxin, especially those points which regulate the innervation of the vessels and the giving out of heat. Less heat is given out and the bodily heat rises. Von Ziemssen secures much clearer views by making his fluorescent screen flexible to fit the contours of the body. He suggests that a cloth vest might be impregnated with the chemicals and fit still more perfectly.

The addresses on "Intestinal Antisepsis" and "Autointoxication" proclaimed the paucity of our knowledge on this subject and the worthlessness of all antiseptics for this purpose. They are only kept in vogue by the advertisements of the manufacturers. Only one or two voices were raised in dissent to this sweeping condemnation, which leaves only prompt evacuation of the contents of the stomach and intestines for our reliance in intestinal autointoxication. Boas remarked that it is usually accompanied by renal insufficiency, and that calomel acts upon both the intestines and the kidneys, while salicylic acid reduces abnormal production of gas. He is now studying the relations between the "oxyacids" and the excretions. Stern related the results of his investigation of calomel feces. They contained so much calomel that in the course of a few hours the bacteria in them were partially or entirely destroyed. Fürbringer also expressed his belief in the value of calomel as an intestinal antiseptic. Albu suggested that autointoxication may be due to spontaneous alterations in the physico-chemical relations in the blood and organic juices, caused by abnormal metabolic products, such as alterations in the osmotic tension. The parallel between exogenous intoxications and the autointoxications *par excellence*: diabetes, gout, anemia, suggests that they are more properly disturbances in the intermediate metabolism; intestinal autointoxication is quite different. Quincke

suggests utilizing the antagonism that exists between different unicellular organisms, and cited his success in treating intestinal putrefaction (with excess of indoxyl and diarrhea) by means of pure yeast, 60 c.c., immediately after each meal. Sternberg announced that the accessorius is the motor and the cervical branches the sensory innervation of the sternocleidomastoides. Van Niesen described a small streptobacterium which he has found regularly in the blood in syphilis and also in specific progressive paralysis and tabes. He ascribes a specific nosogenic importance to it in the probably complex etiology of syphilis. Trumpp asserted that cholera and typhus immune serum produce agglutination, which he considers establishes a connection between agglutination and immunity. It is not a mechanical phenomenon, but due to some effect on the walls of the bacteria, and immunity may be due to this same effect. Badt stated that 94 per cent. of his fifty-three cases of arthritis deformans were women, and in 80 per cent. of these, the affection had commenced with the menopause, to which he is inclined to attribute its etiology. The oöphorin tablet treatment recommended by Senator and others for the climacteric disturbances in the circulation seems indicated, therefore, in this disease.

SELECTIONS.

Medical Charity in New York.—Dr. Frederick Holme Wiggan of New York, presented to the recent Conference of Charities and Corrections, "An Historical Sketch of the Recent Movement to Restrict the Abuse of Medical Charity in New York." He said that the movement had been inaugurated about eighteen months ago by the efforts of Dr. Stephen Smith, recently president of the Department of Charities, and Dr. Landon Carter Gray, then president of the Medical Society of the County of New York, who showed that the ratio of those applying for medical aid had risen from 16 per cent. in 1860, to about 49 per cent. in 1895. A committee of the County Medical Society, consisting of gentlemen representative not only of the general medical profession, but of the larger teaching faculties in the city, were charged with the duty of investigating the question of the abuse, and if possible suggesting the remedy. They found no difficulty in proving the existence of a serious abuse, and consequently their efforts were chiefly directed toward seeking out the remedy. It did not take long to reach the conclusion that the evil was largely the result of a lack of proper methods of investigating the financial condition of those applying for medical relief, and that the Charity Organization Society considered it perfectly feasible to systematically investigate all applicants. The cost of such investigation, it was estimated, would be about \$25,000 the first year, and about \$5,000 each subsequent year. In the opinion of the Committee, another important factor in the production of the dispensary abuse was the system of charging small fees for the medicines and apparatus, thus leading many persons to feel that they were paying their way. As a result of this preliminary study of the question, the Committee felt convinced that the evil could be restricted by attention to these points, and also by making it a misdemeanor, punishable by a moderate fine, for a person to obtain, by reason of false representation as to financial condition, free medical or surgical relief at a dispensary. An effort was then made, by means of a circular letter, to secure the co-operation of the managers of the dispensaries, but although more or less definite replies were received from seventy-six dispensaries, it soon became apparent that it would be impossible to get the managers of all the dispensaries in this city to voluntarily agree to any general plan. The attitude of these managers was clearly presented in the report made to the legislature last January by the State Board of Charities, which says of them: "They apparently are not, and have never been in a temper to come to some mutual understanding whereby better conditions shall prevail. In a large degree, and for various reasons, they have become competitors in business to such an extent that it is probable that nearly half of the inhabitants of New York are now receiving practically free medical treatment." The original committee was soon reinforced by representatives from a similar committee appointed by the New York County Medical Association. As a new organization, known as the New York Society for the Advancement of the Practice of Medicine, had already introduced into the legislature a bill intending to rectify some of these abuses of medical charity, and as this bill contained a number

of objectionable features, its proposers were consulted, and persuaded to give their consent to the substitution of another bill that had been prepared. The main features of the latter or the first "dispensary bill" were: 1, forbidding the establishment of a dispensary in a drug store or tenement house; 2, requiring all dispensaries to be duly incorporated and to be licensed by the State Board of Charities; 3, providing that persons shall not obtain relief from dispensaries by false representations, and that a violation of this act shall be a misdemeanor; and 4, empowering the State Board of Charities to make rules and regulations, and to annul or suspend incorporations, and to revoke licenses. The bill having received the endorsement of the State Board of Charities, it was passed unanimously by both houses of the legislature, but did not become a law owing to the failure of the executive to approve it. Between this time and the opening of the legislative session of 1898, the subject was freely discussed, not only in the medical societies, but by both the medical and lay press, and the following medical societies endorsed the plan of appealing to the legislature to limit the abuse of medical charity: The New York State Medical Association, the Medical Society of the County of New York, the New York County Medical Association, the New York Medical League, the New York Society for the Advancement of the Practice of Medicine, the Medical Society of the County of Kings, the Kings County Medical Association, the Brooklyn Medical Society, the Brooklyn Medical Association and the Long Island Medical Society. Representatives of these societies formed a joint committee which, after much careful investigation, prepared the outline of another bill, which was milder in character, and which seemed to eliminate the features which had been considered objectionable in the previous bill. Before its representation to the legislature, this outline was submitted to the revision committee appointed by the Governor for the purpose of revising or preparing bills, so that they shall be constitutional, and shall not conflict with existing laws.

The essential points of difference between the second bill and this one were: 1, in the new bill the definition of a dispensary was limited to such institutions as derived their income, wholly or in part, from trust funds, public moneys or sources other than the individuals constituting the dispensary and the persons actually engaged in the distribution of its charities; 2, in the new bill the State board of charities was given control over dispensaries by empowering it to grant licenses to such institutions as, in their judgment, would be for the public benefit; 3, in the new bill, the board was given the power to revoke licenses for cause, after a public hearing, instead of, as in the previous bill, the power to annul the act of incorporation. It seemed to the framers of the measure that if the existing abuse of medical charity was to be controlled, the first requisite was an impartial body, which should control and make rules and regulations for the government of all institutions seeking to relieve the sick poor. Such a body is provided for by the legislature, under the constitution, in the State board of charities, and its powers are such that they would require to be but very slightly extended to allow this board to assume control and supervision of the dispensaries of the State by issuing and revoking licenses. This revised dispensary bill was very generally and favorably commented upon by the daily press at the time of its introduction into the legislature in the early part of the session. At first, the bill met with scarcely any opposition in the legislature, but when it was favorably reported by the committee on public health of the senate, to whom it had been referred, such vigorous protests were received by the chairman of that committee, that provision was made for a joint hearing of the friends and opponents of the measure, before the senate and assembly committee on public health. After full arguments on both sides, the senate committee reported the bill favorably to the senate, which passed it with only two negative votes; but the public health committee of the assembly failed to report the measure to the assembly, although vigorous efforts were made by its friends to secure a favorable report. The measure was therefore smothered in committee, and failed to become a law.

Operation for Hour-Glass Contraction of the Stomach from Gastric Ulcer.—Mr. Watson Cheyne has had an important case at the Kings College Hospital, of the above nature, with operation followed by recovery. The hour-glass condition of the stomach is not very infrequently met with at a necropsy, but is certainly rarely that it can be diagnosed clinically. The surgeon holds the opinion that the Heineke-Mikulicz operation which he performed was the most suitable under the circumstances. As more than three and a half months have elapsed since the

operation the hope that the patient is permanently relieved seems fully justified. A married woman, aged 46, was admitted to the hospital on November 8. About six years ago she began to suffer with great pain in the hypochondriac region and in the right shoulder and, in fact, with all the symptoms of ulcer of the stomach with the exception that she had at that time no hemorrhage. She was treated for this condition by diet and in various other ways, and had suffered much from time to time, but latterly the symptoms had been those of obstruction. She was emaciated and feeble and had almost daily vomiting. Her diet had of late been entirely a fluid one. Examination showed a moderate amount of gastric distention that was not uniform. On listening with a stethoscope over the middle of the stomach region, a gurgling could be heard from time to time as if fluid was running through a narrow orifice, and Dr. Burney Yeo, who saw the patient in consultation, stated that in his opinion the case was one of hour-glass contraction of the stomach, resulting no doubt from an old ulcer. On December 1 a vertical incision was made over the stomach, in the middle line, about four inches in length, and when the peritoneal cavity was opened the stomach was drawn out of the wound; it was then found, as had been expected, that just above the center of the stomach there was an hour-glass contraction. The stomach, especially toward the cardiac end, was very considerably dilated and there was also some dilatation toward the pyloric end. The contraction was very marked and when it was laid open it was found that the communication between the two portions of the stomach was extremely small; as a matter of fact, a crow quill could hardly have passed through. There was a good deal of scarring and cicatricial tissue in the neighborhood and at the actual point of the contraction there was no mucous membrane at all. An incision was made through this contracted portion in the line of the stomach so that the ring of cicatricial tissue was divided transversely; this incision was extended into the healthy parts of the stomach for about one and a half inches on each side, and then the angles of the incision were brought together and the rest of the part sewn up, first with a few stitches which went through all coats of the stomach and then with a row of Lembert's sutures; in fact, the operation performed was identical with that employed in cases of contracted pylorus under the name of pyloroplasty. After the operation was concluded an opening was left between the two portions of the stomach, which could readily take a couple of fingers. The wound was then stitched up and the patient put back to bed; she was not very much collapsed after the operation. The wound healed by first intention and the patient went on very well. After about a fortnight she was allowed to have solid food. She was discharged on January 7, having gained eight pounds since her admission, and she stated that she felt better than she had felt for many years; this improvement still continues. She is still somewhat troubled with flatulence, but beyond that her condition is practically normal. She still continues to gain weight. The interest of the case lies first in the diagnosis, that instead of being a pyloric obstruction as had been supposed by other physicians, it turned out to be a typical hour-glass contraction of the stomach. The diagnosis chiefly depended on the absence of the marked dilatation of the stomach, which would occur in pyloric constriction and in the bubbling of the fluid through a narrow orifice, which was heard, not in the situation of the pylorus, but about the center of the stomach. The further point of interest is in the treatment. One was very much tempted to excise the contracted portion of the stomach altogether and stitch the walls together on each side and no doubt that would have been followed by complete recovery without any risk of recurrence of the contraction, for it must be admitted that there may possibly be an increased contraction still and some recurrence of the symptoms, but the patient was in an extremely feeble condition and it did not seem justifiable to subject her to the prolonged operation which would have been involved in this procedure.—*London Lancet*, March 19.

PRACTICAL NOTES.

Gastro-enterostomy for Non-cancerous Stenosis.—Hayem reserves this operation for a last resort after the failure of all medical measures, except in the case of the poor, for whom repose and proper diet are impossible. The hyperacidity will usually disappear if the opening into the stomach is made large enough. If bile flows back into the stomach it may irritate the glands

to a certain extent, so that the ideal operation prevents any retention of food in the stomach and any regurgitation of bile. — *Bull. de l'Acad. de Méd.*, April 5.

Condurango as an Analgesic in Gastric Pains.—The pain accompanying ulcer and cancer of the stomach, etc., can be quieted by administering five to eight pills a day containing ten centigrams each of condurango bark. It often prolongs the life of the patient by facilitating alimentation. Lemoine believes that the condurango, like coca leaves, contains some alkaloid or glucosid, which exerts an analgesic action upon the gastric mucous membrane. It has almost invariably relieved his patients during an experience of several years. — *Semaine Méd.*, May 18.

Bernay's Sponge as a Hemostatic.—At the last annual meeting of the American Laryngological Association, held in Brooklyn, N. Y., May 16, Dr. W. K. Simpson of New York demonstrated the use of the Bernay sponge, which he maintained would swell to fifteen times its size and absorb twelve times its weight of liquids. Its efficacy in general surgery he claimed to be due to the absorbing power, acting as a cleansing agent and then serving to pack the wound. This sponge consisted of cotton fiber subjected to many hundred pounds of pressure and compressed to a disc one-sixtieth of an inch in thickness. It was especially adapted for use in the nares, was an excellent splint for the later stages of Asch's operation for deflected septum and could be used as a means of conveying medication to various parts of the nose.

The Hernias of Children.—Dr. W. B. Coley states that in upward of 300 operations for hernia in children under 14 years of age, he has had but one death, and that was from pneumonia. In seven operations in children under two years of age there was but one death, the patient being moribund at the time of operation. Bassini's method of operation is preferred. In four cases out of seven the cecum was found in the sac. Strangulation in infants is more common than is generally appreciated, and not infrequently arises from the bad advice to postpone wearing a truss until the age of one year. As to treatment, gentle taxis should be tried for one or two minutes; if this fails, applications of hot cloths should be made for them for from fifteen to twenty minutes, followed by taxis under chloroform, after all preparations for operation have been made. If this also is unsuccessful, immediate operation is to be undertaken. An attempt at radical cure can, in the great majority of cases, be made with safety. — *Archives of Pediatrics*, April.

Conservative Manipulation by Gynecologists Advised.—Dr. Howard Kelly has contributed to the *American Journal of Obstetrics* an article upon the needlessness of lacerating the hymen for the majority of gynecologic ailments. He speaks feelingly of the frequency with which the hymen is utterly disregarded, and attributes a much greater want of thought in this respect to female than to male practitioners. He urges that no one but an acknowledged expert should examine a virgin, basing his opinion upon the fact that delicacy of touch is needed to avoid lacerating the hymen, and upon the infrequency of any serious gynecologic lesion in this social condition. He then describes his method of examining virgins. He urges that while a skilled man can usually make a bimanual examination without lacerating the hymen, the latter is so frequently injured by the unskilled that most men should confine themselves to the use of the rectum in virgins, and that the patient should always be anesthetized and after anesthesia should be raised into the knee chest position and held there while air is admitted to the vagina and rectum. If she is then placed upon the back there should be no obstacle to the performance of a most satisfactory bimanual examination through the rectum. He describes a speculum which he has devised for use in the knee-chest position under anesthesia, in virgins. This

speculum is closely similar to well-known Kelly vesical specula, but is fitted with a beveled end in order to avoid the necessity of using an obturator.

Amyloform and Dextroform.—A new substitute for iodoform has recently been prepared by Professor Classen of Aix-la-Chapelle, which he names "amyloform," and which consists of a combination of formaldehyde with starch. It occurs as an almost impalpable white powder, devoid of all smell and insoluble in ordinary menstrua. In contact with the tissues of the living body, however, it breaks up, and when it was applied to extensive suppurating wounds formaldehyde could be detected in the purulent discharge. At the same time the urine was proved to be quite free from it by distillation with dilute sulphuric acid and the addition of fuming sulphurous acid, so that whatever formaldehyde enters the system must be fully oxidized therein. However much amyloform is applied no toxic symptoms are produced, though a slight and transient smarting sensation is sometimes complained of locally. The clinical effect of the substance is very similar to that of iodoform, only it is frequently more pronounced. In a number of cases of deep wounds with suppuration of bone from osteomyelitis or tubercle, a quantity of the powder very liberally applied caused the suppuration to cease in a very short time, in some instances where iodoform had previously been tried without much result. In varicose ulcers of the leg and in the primary sore of syphilis amyloform also proved useful. The above clinical observations were made by Bongartz in the Marienhilf Hospital, Aix-la-Chapelle. It has been mentioned that amyloform is insoluble, but a very similar substance has been prepared from dextrin instead of starch, which Classen calls "dextroform," and this is dissolved without much difficulty by both water and glycerin. Its 5, 10, or even 20 per cent. solution has proved very useful, as in injection in gonorrhea, and the former of these solutions has been employed with success for washing out the cavity of an empyema. Internally the solution has been prescribed with advantage in a case of cystitis. — *Lancet*.

Electric Light in Rheumatism and Neuralgia.—Kozlovski, in *Vratch*, has published an account of his treatment of rheumatism and neuralgia by means of exposure to the electric arc. He was induced to make these observations by the statement of Ewald, who is medical officer to some large iron works, that he had noticed that since the introduction of the system of electric welding there had been a notable diminution in the number of cases of rheumatism, neuralgia, migraine and other nervous diseases among the workmen, which he attributed to the beneficial effect of the electric light. In order to bring this therapeutic agent within the reach of ordinary patients, Kozlovski has fitted up a consulting room with a suitable plant for producing the electric arc, which consists of a six-horse-power oil engine, a dynamo, thirty-five Tudor accumulators, a rheostat, ampere-meter and electric arc lamp with reflector. With these he obtains an electromotive force of 50 to 60 volts and a current of from 250 to 300 amperes. The patient is placed at a distance of one and a half meters from the light and protected by blue spectacles and also by a screen of cardboard in which an aperture is cut to allow the light to fall on the affected region of the body. To this it is exposed for from three-quarters of a minute to two minutes. The patient feels a slight sensation of heat, though the temperature is never raised more than 4 degrees F., where the light falls on the skin, but nothing more until six or eight hours afterward, when itching and tingling are felt and the skin becomes reddened. Some forty-eight hours later, desquamation occurs, which lasts for two or three days. In the course of three months Kozlovski has treated thirty-eight patients, varying in age from 13 to 70 years, by the electric light. There were eight cases of eczema, all of which recovered; four of neuritis (locality not stated), two of which recovered; eighteen of chronic rheumatism, fourteen of which recovered; three of lumbago, all of which recovered; three of occipital neuralgia, of which two recovered; and two of trigeminal neuralgia, one of which was greatly benefited. In most cases three or four sittings produced an amelioration of the pain. They were continued at intervals of three or four days, according to the amount of cutaneous irritation, but the total number of sitting never exceeded a dozen.

Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance	\$5.00
Foreign Postage	1.75
Single Copies	10 Cents.

In requesting change of address, give old as well as new location.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, JULY 2, 1898.

BUBONIC PLAGUE IN BOMBAY.

The plague has always been an interesting field for the litterateur as well as the scientist. The animated description of DE FOE, the child-like simplicity of PEPYS, have made accounts of the ravages of the frightful plague entertaining, and so far as science is concerned it is only necessary to look at the vast number of titles in the Index Catalogues of the Surgeon-General's office to see how much has been written on the subject of the plague. Many of the interesting points in the story we are in the habit of relegating to the past, and to think of these as having occurred at some time during the back ages, but by a report printed in our day we are brought face to face with the same conditions, the same panics, the same disturbances as those which characterized the plague days of the fifteenth and seventeenth centuries.

KHAN BAHADUR DOCTOR CHOSKY, in his report on the Bubonic Plague at Arthur Road's Hospital, Bombay, says: "The first plague patient was admitted on the 24th of September, 1896, and two more following before the end of the month. In the month of October there were 85 admitted, which gradually increased until there were 182 admitted in December, 277 in January and 365 in February. This taxed the hospital to its utmost capacity, as naturally enough with the increase of inmates there must be a comparative increase in the servants and assistants."

Dr. CHOSKY further says:

"Every effort was therefore made to secure additional servants, but in spite of the continuous efforts of the authorities to procure them even on double or treble pay, the greatest difficulty was experienced. There was extreme reluctance on the part of men, who had never been in their lives inside a hos-

pital, to take service, especially in a plague hospital, and when asked, they openly said that they would not endanger their lives under any consideration; some, however, were induced to join but only worked for a few hours or days and then ran away, never even coming to claim their wages. The number and the frequency of deaths, combined with the delirious condition of patients, used to frighten them, and indeed the sights and sounds of a plague ward in the dead of night, with the groans and moanings of the delirious patients, were enough to appal the stoutest heart. Old servants could with difficulty be induced to remain, and a majority of them on that account went on strike and refused to work. All of them were given a bonus to make them continue in service, and their pay all round had to be increased. They were asked to induce some of their own friends to take up work in the hospital, but to no purpose. They used to come, work for a short time and run away as before. Pay however large was no inducement. They had never seen so many people dying as they did in the plague, for the largest number died at the Arthur Road Hospital, both because of the numerous admissions and because so many cases were brought in a moribund condition. It was not until March, when the epidemic commenced to decline, that a considerable number could be induced to join, and strange to say among the latter were some people who had attended their sick friends in the Hospital."

There were three Hospital Assistants who worked practically night and day, Dr. CHOSKY himself putting in from six to seven hours' work every day.

"Apart from these difficulties," says the Doctor, "the Hospital had to contend against the ignorance and prejudice of the people, always averse to going to a hospital, and more so when sent there against their will and under compulsion. Time after time patients in a moribund condition were brought to the Hospital, to whom no relief could be given, as they were practically past all help and they came simply to die, the Hospital getting all the popular discredit attached to the heavy mortality. Nearly one-third of the total admissions during the six months died within twenty-four hours of admission, by far the greater number dying within a few hours and some even within a few minutes. At times patients were found dead when brought to the Hospital in ambulances, and the corpses were sent direct to the burning grounds. Added to this heavy mortality, the means used to resuscitate and support their strength, especially subcutaneous injections, were misconstrued, and it was openly said that the doctors were killing the patients in order to stop the further ravages of the epidemic. It was also freely stated that the patients were purposely killed and their hearts taken out in order to send them to Her Majesty, the Queen-Empress, to appease her wrath on account of the disfigurement of her statue, which occurred in the beginning of the epidemic. All this culminated in a raid on the Hospital in the forenoon of 29th of October, 1896, when a large number of mill-hands, estimated from 800 to 1000, rushed toward the Hospital, breaking open the gates and scaling the walls with a view to wreak their vengeance on the Hospital staff for the alleged killing of patients. Road metal was freely thrown at the Hospital staff, some of which reaching the wards, broke the tiles and injured some patients, but fortunately no one was seriously hurt: on learning that the police were approaching, the men dispersed in all directions. An armed police guard had to be quartered on the premises for a long period and Arthur Road, which is one of the main roads leading to the mills, was patrolled by mounted and foot police for a considerable time after the raid. The Hospital assistants were openly threatened with violence; they dared not go out of the compound for their meals, etc., unless shadowed by policemen in plain clothes, and it was under such conditions

that the work of the Hospital was conducted for some two months."

The usual crop of charlatans seemed to develop, following in the wake of the victims of the plague like vultures after a battle. The report says:

"The plague epidemic had suddenly created in our midst a host of pseudo-specialists who pretended to know all about the plague and who for a time, forgetting their usual avocations of tramway conductors, railway guards, engineers, postal inspectors, clerks, etc., suddenly blossomed forth into plague specialists, vaunting their nostrums day after day, and pestering the health officers as well as the medical officer of the hospital. Then again, the permanent quacks had their specialties, and in some cases even duly qualified medical men, who ought certainly to have known better, came out with strings of prescriptions and specifics with the view of obtaining a fleeting notoriety."

Being in India instead of America, we suppose the Doctor was spared the spectacle of seeing photographs of these people staring at him from every edition of the daily newspapers.

Of the hospital staff the assistant medical officer, Dr. P. N. DAVDA, and three ward boys were attacked with the plague. Dr. DAVDA unfortunately died, notwithstanding the naïve remark in the report (page 45), in speaking of preventive treatment: "None of the hospital staff were inoculated with Professor HAFKINE's preventive serum. The late Dr. DAVDA had, however, 10 c.c. of Dr. YERSIN's serum injected as a preventive about three weeks previous to his illness."

Preventive treatment in the hospital was directed toward lessening the risk of infection among the hospital staff and ward attendants who came in contact with the sick. Free ventilation, frequent disinfection of the hands, frequent changes of clothing were required. Floors were sprinkled with chemie disinfectants. The clothing and other belongings of the patients were destroyed by fire, and it may be assumed that this treatment was successful, inasmuch as but three of the attendants had the disease. As to the different methods of treatment, the author is of the opinion there is no specific treatment.

In regard to postmortem appearances, the author says: "If it were possible to convey in one word the principal postmortem signs of the changes that are found in the system, that word would be hemorrhage. Hemorrhages in every conceivable and inconceivable part of the body."

Our space is too limited to quote more from this very interesting report, a report which deals with the total number of cases, 939 in the short space of five months, a report so evidently written from a full knowledge of the disease that it will be turned to for many years to come as an authoritative treatise on the plague; therefore in sharp contrast with the emanations from the public press on this subject purporting to come from a certain official sanitary bureau, photograph of the incumbent duly attached.

INHERITANCE OF CIRCUMCISION EFFECTS.

No question in biology has been discussed with more animation than that of the transmission by heredity of acquired defects. Prominent among those who denied hereditary transmission of acquired effects was WEISMANN. His writings have been received with much favor and he has won a very numerous following. The effects produced by his criticisms have been undoubtedly beneficial in removing from certain ideas of heredity their crudeness. The older notions of heredity were much more vague and at the same time more sweeping than those held by modern biologists. WEISMANN's followers have cleared up much obscurity, but at the same time by too intense devotion to a theory have added even more. WEISMANN for example rides the germ hobby to death, in his attempt to explain the transmission by heredity of traumatic epilepsy in guinea pigs. He assumes that epilepsy is always of microbic origin. The reason therefore that the mother most transmits epilepsy is because the ovum being larger than the spermatozoon it necessarily carries more microbes of epilepsy than the latter. As his explanation fails to demonstrate that epilepsy is of microbic origin, it utterly fails not merely to exclude all other hypotheses but even to explain the facts themselves. This is a fair illustration of the weakness of WEISMANN's position in regard to the transmission of acquired defect.

Indeed such evident transmission has forced him to a concealed though rather complete reversal of his absolute position on the subject. In his latest work ("The Germ-Plasm," p. 535) he admits that nutrition of the germ-plasm will modify heredity. As nutrition of the germ-plasm depends, according to WEISMANN on the state of nutrition of the spermatozoon and the ovum it is obvious that this must depend on the state of nutrition of the male and female producing these. It is therefore evident that the state of mental and physical health of the parents will modify the offspring despite the tendencies to continuity of the germ-plasm on which such stress has been laid by WEISMANN. One of the "facts" on which the strongest stress has been laid by WEISMANN and his followers as an argument against hereditary transmission of defects, is that of circumcision. WEISMANN admits it is certainly true that among nations which practice circumcision as a rite ("Heredity," Chap. 8), children are sometimes born with a rudimentary prepuce. This however, according to WEISMANN, does not occur more frequently than in other nations where circumcision is not practiced as a rite. The truth of this last assertion is seemingly supported by instances recently appearing in the literature. P. C. REMONDINO of Los Angeles, California, has seen a large number of cases ("Circumcision") of prepuce absence in Hebrews which prove to be hereditary. After one confinement in a Gentile his attention was

called to the child by the nurse. She thought it was deformed because of the size and appearance of the glans penis. On examination the prepuce was found to be completely absent. On inquiry the father, and another son born more than two decades previously (these comprising every male member of the family), were found to have been born with the glans fully exposed. REMONDINO has seen a French family in which there was similar heredity.

The statements about the non-transmission by heredity of circumcision effects have been so strongly reiterated that it is hardly astonishing that they were long accepted and the non-inheritance referred to the healthy atavism of the maternal side. Of late these assertions of WEISMANN and others as to circumcision non-inheritance have been questioned. Dr. WILLIAM WOLFE of Baltimore some years ago (*American Medico-Surgical Bulletin*, 1895) reported as the results of long research that two per cent. of the Hebrews coming under his observation were born without a prepuce, and that a much larger proportion had defective ones. Stimulated by his researches Dr. EUGENE S. TALBOT of Chicago was led (*Medicine*, June 1898) to institute an inquiry as to the conditions of the prepuce found by the Hebrew clergymen of Chicago engaged in performing the religious rite of circumcision. He found that the percentage obtained by Dr. WOLFE was not as great as that occurring in Chicago. He obtained results from the Rev. Drs. S. BAUER, M. A. COHEN and B. GORDON. Dr. BAUER had circumcised 3400 and found that the prepuce was absent in $3\frac{1}{2}$ per cent. of the cases. Dr. COHEN had circumcised 10,000 times. He had found the prepuce absent in 500 cases; partially developed in 300 cases and slightly developed in 2000 cases. Dr. GORDON had performed 4400 circumcisions in 25 years. He had found the prepuce absent in 150 cases; partly wanting in 200 and slightly developed in 2200. These, it should be remembered, were cases where preputial deformity casually forced itself on observers who were not pursuing special investigations as to the inheritance of the results of circumcision.

Considering the emphasis with which the non-inheritance of the preputial effects of circumcision has been reiterated, the most astonishing result of Dr. TALBOT's researches was the discovery that rabbinical literature contained disputes on the subject of the religious treatment of cases where the child had been born circumcised. There was very early a difference of opinion on this subject between the schools of Shammai and Hillel. The school of Shammai maintained that if a child be born circumcised it is still necessary to draw from him the dram of covenant blood; the school of Hillel maintained that this was not necessary. According to another authority this point was not involved in the discussion since both schools were of the opinion that where a child had been born circumcised the drop of the blood of

the covenant had still to be drawn from him on the eighth day. The dispute related however to an adult proselyte who happened to have been born circumcised. In this case the school of Shammai insists upon the ritual drawing of blood. The school of Hillel claims that ritualistic drawing of blood was in such case unnecessary.

In the Medrash (the homiletic commentary of the Rabbis on the Old Testament) nearly every prominent man mentioned in the Bible as well as some of the later prominent rabbis, are stated to have been born circumcised. Among these were MOSES, SAMUEL, ISAIAH and Rabbi AKIBAH. The law relative to children born circumcised was codified 1567 A.D., in the Schulchan Aruch. Joreh Deah, Hiletroch Milah, Beth Shammai and Beth Hillel quoted in it flourished between 70 B.C. and 70 A.D. These results of Dr. TALBOT render it clear that not only does circumcision produce inherited defects more frequently among the Hebrew than among other races which do not practice circumcision but that this has occurred to such an extent that the treatment of such cases has long been recognized as a subject for discussion in the religious literature of the Hebrews.

REGIMENTAL HOSPITALS IN FIELD SERVICE.

As a people we are learning by experience that it takes time to turn out a volunteer army of 125,000 men fully armed and equipped. Early in April, when the war cloud was gathering, we read in our newspapers about the active work of preparation going on in the armories, and how this and the other regiment was ready to take the field at an hour's notice. In fact, we were led to believe that when the call to arms should sound the quota of each State would be ready to fall in. And grave doubts arose in our mind as to whether, in the short time that would be needful to form the regiments into brigades and divisions for purposes of field command, the medical department would be able to put itself on a fighting basis with field hospitals and ambulance companies properly manned and efficiently equipped. We were aware that however well drilled a company or regiment of citizen soldiers may be, some little time in a camp of instruction is needful before they can form an efficient part of an army. Besides purely military drills, the men have to learn how to live in canvas shelters carried by themselves, and even how to cook for themselves when the wagons can not come up with the mess-chests and camp-kettles; and the officers have to learn how to utilize the army ration that their men may have as full and varied a diet as may be found in the company messes of our regular troops. But we doubted whether the time required for these purposes would suffice to enable our military brethren to get ready their system of organized relief for the sick and wounded of a large army.

However, the mustering in of the men, associated

as it was with a strict medical examination, took much longer than was anticipated; and when mustered in and transported to war camps at Chickamauga and Washington, and even nearer their possible battle-fields, as at Tampa, Fla., it was found that there was still much to be done that must consume time before the regiments could be considered fit to undertake the field duties of soldiers. Meanwhile the Medical Department has been utilizing the time to the best advantage. The hospital corps has been recruited by enlistments and transfers from the line, medical and hospital supplies have been provided, ambulance wagons have been built and distributed and the organization for field service has been progressing on the lines outlined by us in the JOURNAL of May 21. Lieut.-Colonel B. F. POPE, U. S. Vols. (Major and Surgeon U. S. A.), chief surgeon of the Fifth Corps, at present before Santiago de Cuba, has perfected his organization and is ready to meet any of the emergencies of military life in time of war. The troops of this corps are mostly regulars and their medical officers are accustomed to obey orders, so that Chief Surgeon POPE has found it an easy matter to perfect his organization.

It is not so, however, with Lieut.-Colonel A. C. GIRARD (Major U. S. Army), chief surgeon of the Second Army Corps at Camp Alger, Falls Church, Va. In our recent discussion of the subject of organization we showed that the regiment is too small a unit on which to build a satisfactory medical service for the care of the wounded of a great battle. The regimental hospital is an excellent institution when a regiment of the National Guard goes into camp for a ten days' summer picnic, or even when called out for duty as a State public force; but it is valueless when an army corps of twenty-seven regiments is drawn up in line of battle. Wherefore, when the new regiments arrived at the camps of organization and instruction, the duty of the chief surgeon was to prepare the medical department of the corps for field service by breaking up the regimental hospitals and organizing the medical relief by divisions. The Second Army Corps consists wholly of volunteers, and certain of the regimental medical officers have taken exception to Dr. GIRARD's efforts to prepare them for war service. They object to having their hospitals broken up and their regimental medical service turned into a mere dispensary service, although the seriously sick receive the best medical attention which the division can provide. Yet some of the volunteer colonels have espoused the cause of their medical officers and protested to the War Department against the change of method. This action of local commanders has so emboldened one of the medical officers that, according to newspaper accounts, he has declared that his hospital shall not be broken up until the whole military strength of his State has been overpowered.

It is to be regretted that medical men who have voluntarily offered their services to aid the Medical Department of the Army in caring for the sick and wounded of the war, should be the obstacle to a proper organization by their failure to recognize any conditions in the present different from those of the summer picnic; but fortunately this difficulty in the Second Army Corps appears to be an isolated experience, for we have heard of no trouble in the organization of the medical departments of the other corps of the Army.

CACHEXIA OF MALIGNANT TUMORS.

The condition of emaciation, anemia and general prostration which accompanies many of the malignant tumors was formerly believed to be a specific symptom of the disease and was called cachexia. Even earlier, the condition, under the general name of a dyscrasia or diathesis, was supposed to precede and induce the growth of malignant tumors. At the present day as well, cachexia is considered by many to be one of the essential symptoms of a malignant growth, yet this opinion must be much modified in the light of observations made upon any given series of patients suffering from malignant tumors.

Cachexia is a term also used to express the condition of patients suffering from a variety of chronic general diseases, such as insufficient food, chronic septicemia or intoxication, leukemia, Addison's disease and anemia. In these diseases there is a general disturbance of metabolism which is chronic in its course and unassociated with temperature. There is an excessive waste of proteids and fats in all of the organs of the body with a resulting condition of malnutrition and weakness; fat disappears from the body; the blood is altered in its composition to produce a pale, anemic appearance to the skin; edema may be present; the patient is feeble and emaciated and the prostration may become extreme. These symptoms are the same that are assigned to the cachexia of malignant tumors, and, in a study of those malignant cases in which cachexia is present, it will uniformly be found that there is, either some interference with the proper nutrition of the patient by reason of the location of the tumor, or there is an absorption of deleterious materials, a chronic intoxication from ulceration, sloughing or degeneration in the tumor.

The most typical examples of cachexia, it will be remembered, are seen in cases of carcinoma of the stomach, esophagus and intestine, where the assimilation of food may be almost entirely prevented. As has been previously stated, insufficient food alone may produce a condition of cachexia, and it is easy to understand how a carcinoma of the esophagus or pylorus, no larger than a walnut, may produce a total obstruction. In carcinoma of the body of the stomach a similar malnutrition is present, because very little nitrogenous food can be digested in the absence of

free hydrochloric acid and rennet. A fact in favor of such dependence of the nutrition upon diet is found in the marked decrease of the cachexia after a gastrostomy has been performed for carcinoma of the esophagus.

Secondly, those cases of cauliflower carcinoma of the cervix, ulcerating carcinoma of the breast and huge sloughing sarcomata, form another class giving prompt and decided cachexia. In such cases it is a plain surgical question of septic intoxication by the toxalbumins of the bacteria of decomposition, which are developing in the necrotic tissue, and it is a fact that, when such a mass is freely curetted away and the field maintained aseptic, as is possible in the inoperable cauliflower carcinomata of the cervix, the symptoms of cachexia disappear. Furthermore, from such ulcerating surfaces there is a continuous discharge and this escape of albuminous material from the body must act injuriously on the system.

The pain accompanying many forms of malignant tumors often deprives the patient of his sleep, and the mental worry together with the universal horror of cancer must contribute much toward the failing nutrition. The demands made by the rapid growth of such tumors upon the nutritive supply of the body can not have a very great influence upon the general body nutrition, because the drain made by the simple growth is not, under ordinary circumstances, very considerable. It must be remembered that, clinically, the most malignant of tumors do not, as a rule, give rise to cachexia, unless they have undergone degenerative change or are so situated as to prevent food assimilation. Patients the subject of operation for a third extensive recurrence, or in the presence of tumors of long standing, usually have no cachexia when such conditions of degeneration or obstruction are not present.

Whether the tumor itself manufactures substances which are poisonous to the body in general is unknown. RINDFLEISCH assumes that the normal epithelial cells aid in the elimination of certain chemie substances from the system. When, however, these cells are enclosed in spaces in the interior of the tissues, as in cancer, the substances can not be thrown off, and at the same time the products of the degenerative processes that are going on in the growth are carried into the circulation, and they exert a poisonous influence upon the blood.

THE IMPORTANCE OF CLOTHING IN WAR.

Medical men on reading the heading of this article would naturally think that we purposed referring to texture, porosity, conductivity, and with Cuba and the Philippines constantly in mind, to the importance of protection from chill; but clothing is important from another point of view as was brought to our notice by a column in the *Daily Mail* of May

11, 1898, on "Why British Officers in India are so Often Killed." Captain NORRIS, M.P., holds that as these officers wear a different head-dress from that of the native officers and troops under them, they are rendered especially distinguishable to the enemy's marksmen. This danger in modern warfare has long been recognized in Europe; but in native regiments in India where all but the English officers wear an Eastern head-dress while the pith helmets of the latter are a fatal distinction. It is gratifying to know that the needful protection has been given to our Volunteer officers on field service. General Orders No. 39, of May 9, 1898, from the Headquarters of the Army, prescribe a light brown blouse of cotton drilling or khakie, with trousers of the same color, for all commissioned officers from the major-general commanding down. As the campaign hat is similar to that worn by the enlisted men, and the insignia of rank require close inspection for their detection on the collar and flat strap on the shoulder, the officer, from the point of view of the enemy's marksmen, is indistinguishable from his men. This will have an important bearing on the make-up of the nominal killed and wounded when such have to be rendered by the medical officers of our Army.

THE ROENTGEN RAY IN WAR SURGERY.

The English papers of May 21 give considerable space to a lecture delivered on the previous day before the Royal United Service Institution by Surgeon-Major BEEVOR of the army medical staff. The object of the lecturer was to give his experience in the working of the X-ray in military surgery, and to show by the results obtained in the recent frontier expedition in India that the apparatus can be carried on a campaign and be of the greatest possible benefit to the wounded. He maintained, in view of his success, that it was the duty of every civilized nation to supply its wounded in war with an X-ray apparatus, among other surgical aids, not only at base hospitals but close at hand wherever there might be fighting. There is no doubt of the desirability of having this aid in field hospitals nor of the possibility of furnishing it for the field hospital of a particular expeditionary force, but we doubt the ability of any army medical department, with our present experience of the X-ray, to have it available in the field hospitals of a large army during the hours of activity that follow the incoming of the wounded from a great battle. Surgeon-General STERNBERG has provided the apparatus for the Philippine expedition, for the hospital ship *Relief* and for the general hospitals to which the wounded from the field hospitals will be sent for treatment; and the experience thus gained in its applicability to war surgery may lead hereafter to a further extension of its use on behalf of the wounded in war.

CORRESPONDENCE.

WAR CORRESPONDENCE.

BY LIEUT.-COL. NICHOLAS SENN, U. S. VOLS.,

CHIEF SURGEON SIXTH ARMY CORPS.

CHICKAMAUGA, GA., June 22, 1898.

CAMP GEORGE H. THOMAS.

From early dawn until taps, Camp Thomas is the scene of a busy, active life. It is the gathering point of the largest army concentrated in one place since the War of the Rebellion. It is at the present time the temporary home of 45,000 men representing almost every State in the Union. Many of the regiments are short of their quota, and recruits to the number of 500 on an average arrive daily to complete the organization of the regiments now in camp. The commander of the whole army in camp is Major General John R. Brooke, General in Chief in charge of the Department of the Lakes. He came here from Chicago with his entire staff. He enjoys the reputation of being a strict disciplinarian who does everything through the legitimate military channels. The greatest source of confusion and consternation to the officers of the volunteers from civil life are these mysterious military channels which extend from the General's tent to the heads of the many departments in Washington. One of the blue books in constant use by officers, high and low, young and old, is the U. S. Army Regulations, 1895. The thousands of questions asked the professional soldier daily by his less informed volunteer officer are answered more often than otherwise by "Study the Regulations, *Study the Regulations*, STUDY THE REGULATIONS." Such advice, as a rule, is more easy to give than to follow with any expectation of approval at headquarters. The experience here has satisfied me more than ever that the National Guard officers need more thorough training in executive, clerical work, so essential in the efficient management of troops at home and in the field. One of the common sights in camp is to see an officer hide himself away under a solitary tree and pore over a work on tactics or the much feared "Regulations." If this war does nothing else but demonstrate to our people and to the legislators, State and National, the necessity of a well organized militia it will have accomplished a great deal. If we had in this country, as we ought to have, a well organized, well equipped militia force of 200,000 men, we would have been in possession of all the Spanish islands and Spain itself, if we wanted it, long ago. As it is, it takes two millions a day and the hardest kind of work to bring our volunteers into fighting trim. The officers of the regular army have reason to be thankful to Spain for having given them a chance to fight. They have been looking a long time anxiously for such an opportunity. They are the recognized salt of the army. The Government has fully recognized their claims. Nearly every day the newspapers bring columns of names of lucky officers who have been advanced in rank, in fact it seems almost impossible for any one of them to escape promotion of some kind. This is probably as it should be, but occasionally such promotions lead to giddy heights. To make a lieutenant-colonel out of a second lieutenant of very limited practical experience is a transition of doubtful propriety and often followed by the most detrimental results, both to the over-ambitious officer and the over-confiding troops placed under his charge. Officers thus honored by promotion and assigned to the army of volunteers are, as a rule, more anxious to change the shoulder straps than to add the V. to the U. S. on the collar of the blouse. On the whole, the regular army officers are perfect gentlemen and great favorites in the camp, and the feeling between them and the officers from civil life is of a most cordial nature.

The First Army Corps under General Brooke is nearly completed. The Third Army Corps under command of Major-General Wade is nearing completion. The Sixth Army Corps is

soon to be organized under Major-General James H. Wilson. General Wilson gained an enviable reputation during the late war as a dashing cavalry officer and will undoubtedly make a creditable record during the present war if it lasts long enough to bring his army into the field. Lieut.-Colonel Hartsuff, an experienced medical officer of the regular army, is Surgeon-in-Chief of the army gathered here, and as such is attached to the staff of General Brooke. Lieut.-Colonel Van Hoff is Chief Surgeon of the Third Army Corps, and has worked incessantly in completing the organization of the medical department under his supervision. He is regarded as one of the ablest executive officers of the medical service, and is known as a warm friend of the medical officers of the National Guard. He has from the very beginning taken a deep and active interest in the work of the Association of Military Surgeons of the United States. Every medical officer of the Third Army Corps should consider it a great privilege to serve under Lieut.-Colonel Van Hoff. The medical department of the First Army Corps is in charge of Lieut.-Colonel Heidekoper of New York, a hard-working, conscientious officer. Major Kimball of Marion, Ind., and Ma-

Major-General John R. Brooke.

General in Chief in charge of the Department of the Lakes.

Major Woodbury of New York, have reported here and are awaiting with the writer the formation of the Sixth Army Corps. At present my time is profitably occupied by consultations in the camp and by performing operations in the Leiter General Hospital and the St. Vincent's Hospital, Chattanooga. The evenings are occupied by giving lectures on first aid to the Hospital corps. St. Vincent's Hospital has been used as a temporary hospital for the troops until the Leiter Hospital was in condition to receive patients. The abandonment of regimental hospitals meets with the same opposition here as elsewhere, but the wisdom of such a course must be apparent to all who have had experience in the field. Major E. C. Carter, U. S. A., is now in charge of the Leiter General Hospital. He is one of the busiest men in the camp. He is in every way admirably adapted for the position he now occupies. He is straining every nerve to improve and equip the building for the accommodation of from 300 to 500 patients. He has the hearty co-operation of the Surgeon-General and Colonel Hartsuff

in pushing the work. About thirty patients are at present in the hospital and in less than two weeks the number of patients will exceed one hundred. Hospital furniture and supplies are arriving every day, and in the course of two weeks the hospital will be fully equipped. The value of this hospital to our sick soldiers can not be overestimated. Mrs. Leiter will have the respect and sincere gratitude of every one of the inmates and of hundreds yet to come. Chickamauga is a quiet little country hamlet where our patients can enjoy to the fullest extent what they are so much in need of, rest and quietude. Six trained nurses have been sent by the Surgeon-General and are now on duty. With the increase in the number of patients more will be sent. A corner room in the tower on the second story has been set aside as an operating room and is now undergoing the necessary repairs to adapt it for this purpose. The first operation performed in this hospital was for empyema following pneumonia. Two additional cases await a similar operation during the course of the week.

Major-General James H. Wilson.

CRAWFISH SPRINGS.

One of the great attractions near the National Park and adjacent to the Leiter General Hospital is the famous Crawfish Springs. At the end of a large basin and at the base of a rock a large volume of water, as clear as a crystal, is poured out with considerable force. This spring yields 62,000,000 gallons of water in twenty-four hours. The temperature of the water is 56 degrees F., summer and winter alike. The dam a little below the springs, utilized to furnish water power for the hotel, has been removed for the reason that it interfered with the supply of water, deviating it evidently through subterranean channels in another direction. As soon as the property was transferred to Mrs. Leiter for Government use I had the basin cleaned out of moss and dirt by a detail of soldiers furnished by the Fifth Illinois Infantry. The sides of the hill around the basin were ditched a few feet above the level of the water for the purpose of draining the surface water to a safe distance below the springs. The Hospital is supplied with water from this spring. Besides, hundreds of barrels of water are brought daily into the camp by mule teams. The water is wholesome and palatable.

The following is the result of a chemical analysis made by a competent chemist:

ANALYSIS OF CRAWFISH SPRINGS WATER.

Bicarbonate of lime.	0.6753
Bicarbonate of magnesia	0.4544
Sodium chlorid.	0.856
Potassium chlorid.	0.048
Silica.	0.0537
Free ammonia.	0.0029
Albuminoid ammonia.	0.0025
Oxygen absorbed.	0.031

The presence of free ammonia and albuminoid of ammonia, although small in quantity, led us to suspicion the presence of organic matter which might possibly prove to be a source of danger. For the purpose of testing the water still further as to its fitness for hospital and camp use, samples were sent at three different times to the professor of chemistry in the Chattanooga Medical College. Dr. H. Berlin made a very careful chemic analysis and bacteriologic examination with the result that he pronounced the water free from dangerous organic matter and pathogenic microbes. The only microbe which he was able to cultivate was the colon bacillus, and the presence of this microbe could be readily accounted for by the blocking of the sewer pipe, an evil which was promptly removed. The springs would furnish an ample water-supply for the whole army if the Government would only erect a pumping station near it, a project which is now under serious consideration. With such an improvement Camp George H. Thomas would be one of the most salubrious camping places in the United States for a large army. The intake now is some distance below the springs where the flow of water is impeded by a dam two miles and a half below the springs. Above the dam is a narrow beautiful lake two miles and a half in length, extending to near the springs, which is leased by the Chickamauga Fishing Club.

CHATTANOOGA MEDICAL SOCIETY.

This medical society meets twice every month, on the first and third Friday. At the last meeting the subject selected by the committee was "The Modern Treatment of Gunshot Wounds in Military Practice." The writer was invited to open the discussion. After a brief résumé of the character of wounds inflicted by the modern bullet, the treatment was considered in detail. Special stress was placed upon the inutility of the ordinary and Nélaton's probe in locating and finding bullets lodged in the body. Attention was called to the value of the X ray as a substitute for the probe in making a reliable diagnosis. The use of the bullet probe on the battlefield was condemned and the advice given that bullet wounds should be hermetically sealed with the first aid package, which should contain an antiseptic powder composed of boracic acid and salicylic acid (4:1), and no exploration made until the patient reaches the field hospital, where all facilities for aseptic surgery and the necessary instruments for diagnosis and operation should be at hand. A new bullet probe and bullet forceps devised by the writer were exhibited and their manner of use explained. The balance of the paper treated of gunshot wounds of the extremities, cranium, chest and abdomen. For want of time consideration of the last subject, "Gunshot Wounds of the Abdomen," was postponed until the next meeting. Invitations to attend the meeting were sent to the military surgeons in camp, consequently the attendance was large and the discussion became general and proved of interest to all present. Considering that Chattanooga has only 40,000 inhabitants and that the average attendance at these meetings on ordinary occasions is never less than from thirty-five to forty, is the surest indications that our colleagues in this city take an active interest in the scientific work of the profession.

AMUSEMENTS.

The civilian soldier finds it difficult to satisfy his mind and body with what is required of him in camp life. But a few weeks ago he was a professional man, a clerk, teacher, or left

the school, workshop and plow, and now it is hard for him to imagine that he should not be kept busy from sunrise to sunset. He is only too anxious to drill in sunshine or rain, and considers it a privilege to do guard duty, where his power and military significance can be made to appear at greatest advantage. He finds it difficult to occupy his many leisure hours in a profitable manner. To the credit of our soldiers it must be said that evidences of intemperance are rarely seen in camp. Temperance canteens are common and are better patronized than those in which beer is sold. I have not seen an intoxicated soldier since I arrived in camp. The more common amusements of the soldiers during the heat of the day, between 10 A.M. and 3 P.M., between drill hours, consists in reading, writing letters, playing cards, and the college boys are bound to play base- or football. The chaplains make themselves useful not only in caring for the spiritual welfare of their soldiers, but they also look after their intellectual interests. They extemporize reading rooms and supply them with writing and reading material. These reading tents are very

Major-General Joseph C. Breckinridge.

popular, and when the men are off duty they are always crowded. The many regimental bands furnish excellent music, which does so much in cheering up and amusing the soldiers. Two theaters have sprung up in the camp, mushroom-like. Performances are given in the afternoon and evening. The admission fee is twenty-five cents, box seats fifty cents. I have been told by those who have been in the habit of attending that the plays are good and that the patrons are made to feel that they have received their money's worth.

RED CROSS ASSOCIATION.

The Medical Department during the present war is in a condition fairly well prepared to supply the sick and wounded with the necessary instruments, medicines and food. There will be only a very limited field of usefulness for the Red Cross Association to fill in defects here and there as occasion and circumstances may require. The work of the Red Cross Association is, however, recognized by the War Department, as becomes evident from a circular letter received a few days ago from the Surgeon-General:

SURGEON-GENERAL'S OFFICE, WASHINGTON, June 9, 1898.

Lieutenant-Colonel Nicholas Senn, Chief Surgeon, U. S. Volunteers, Sixth Army Corps, Chickamauga Park, Ga.

Sir:—The Secretary of War has approved the following

proposition made by the American National Red Cross Association, and the chief surgeons of Army corps and divisions will co-operate with the authorized agents of this Association for the purposes indicated:

"We can put any desired amount of hospital supplies—ice, malted milk, condensed milk, Mellin's food, etc., into any of the volunteer camps in a few hours. Will you be kind enough to bring this letter to the attention of Secretary Alger and ask him if there is any objection to our appointing a Red Cross representative to report to the commanding officer and the chief surgeon in every camp, confer with them as to their immediate needs and, if anything of any kind is wanting, open there a Red Cross station and send in the supplies. We can do this, not in a few weeks or a few days, but in a few hours, and can furnish any quantity of any desired luxury or delicacy for hospital use. We hereby tender our aid and put our organization at the War Department's service for co-operation in the field."

Very respectfully,

GEO. M. STERNBERG, Surgeon-General U. S. A.

It was prudent and wise that the Surgeon-General and the Secretary of War granted this modest request. Dr. Gill of New York represents the Red Cross Association here. He arrived a few days ago and intends to erect a frame building near the general headquarters as a storehouse for the supplies. He possesses excellent executive abilities combined with modesty, which will ensure him a wide avenue of usefulness and the hearty appreciation of the medical officers. In my next communication I will speak of the hospital corps, its organization and scope of work in actual warfare.

Belladonna Poisoning Simulating Puerperal Insanity.

NEW YORK CITY, June 25, 1898.

Mrs. G., 26 years old, was delivered last January of an anacephalous male child. Labor was short and natural. Two days after, to prevent the secretion of milk with the consequent painful distention of the breasts, a belladonna plaster was applied to each gland in addition to the usual bandage compression. The nipples were not covered by the plasters. In about twelve hours I was hurriedly called to my patient and found her condition as follows: Flushed face, pulse 100 and good; temperature 100.5 degrees and quite actively delirious. She sang, whistled, laughed, cried and made futile attempts to get out of bed and house. Finding no appreciable cause for the combined disturbance of body and mind, puerperal insanity suggested itself as the most probable diagnosis.

The second visit was made sixteen hours after the first; the woman's condition was found to be much worse, namely: Her delirium was intensely maniacal in spite of the fact that she received large and frequent doses of chloral and bromid. However, at this visit new features were added to the old clinical picture which at once removed the diagnosis of insanity and established one of belladonna poisoning. The patient's lips, tongue, mouth and throat were dry, the pupils fully dilated and the secretion, as urine, was almost totally suppressed.

The belladonna plasters were quickly removed and the breasts washed with soap and water. The breasts were examined for a scratch or an abrasion which could serve as an avenue for absorption, but as none was found the drug evidently found its way into the system through the unbroken skin.

All the symptoms disappeared within ten hours of the removal of the cause excepting the pupillary dilatation, which lasted thirty-six hours.

It may be interesting to add that the very same condition was produced in the same patient four days later by the application of one plaster only and the removal of which resulted in the removal of the trouble.

The points of interest in this report appear to be these: 1. The remarkable susceptibility of this woman to the influence of belladonna. 2. The minimum amount of the drug which produced the symptoms of poisoning. 3. The possibility of mistaking that condition for acute insanity when it occurred in

the puerperium. 4. The caution to be observed in prescribing belladonna plaster or ointment—an old warning, but one that can bear repetition.

R. ABRAHAMS M.D.

An Explanation.

PHILADELPHIA, June 16, 1898.

To the Editor:—We note the letter recently addressed to your JOURNAL (May 28, p. 1301) by Dr. J. H. Davisson of Los Angeles, Cal., ex-president of the State Board of Health, relative to an irregular use of a recent report made by him, which was published in our antitoxin brochure about a year ago.

It was far from our intention to cause Dr. Davisson any annoyance, or to make any improper use of his name. It was not our intention to have it appear that the Doctor personally endorsed our product, but that the State Board of Health of California discriminated in favor of American antitoxin, and since, at the time our brochure was published, we were supplying, and have continued to supply, the California State Board of Health with Mulford's Concentrated Antitoxin, the statement as published in our brochure is correct. Our copy supplied the publisher, incorporated the above with a quotation from Dr. Davisson's report. Unfortunately, our instructions regarding the use of the bracket were not carried out. The article should have read according to our copy as follows:

CALIFORNIA STATE BOARD OF HEALTH.

The antitoxin used in California is made in this country and after considerable investigation and trial of the German and French products, we are giving our preference to the American production. The American product is put up in better form for transportation and handling, which is of itself an important item. [The antitoxin now used by the Board is that of H. K. Mulford Co. of Philadelphia. The concentrated "Extra Potent" (500 units to each c.c.) is the best.]

We extremely regret that the bracket was omitted in placing this matter in type. Certainly we did not intend to have it appear that our product was personally endorsed by Dr. Davisson, but the fact that the California Board of Health was being supplied with Mulford's Antitoxin at the time our brochure was published, makes the statement as appears in our brochure, with the exception of the personal endorsement of Dr. Davisson, absolutely correct.

Thanking you in advance for the publication of this explanation, we are Very truly yours, H. K. MULFORD COMPANY.

Marine Hospital Service.

TREASURY DEPARTMENT,
OFFICE OF THE SUPERVISING SURGEON GENERAL
MARINE-HOSPITAL SERVICE.

WASHINGTON, D. C., June 24, 1898.

JOURNAL AMERICAN MEDICAL ASSOCIATION, 61 Market Street, Chicago, Ill.

Sirs:—With the close of the present fiscal year, June 30, the subscription for eighteen copies of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, for the use of this Service, will expire, and will not be renewed for the ensuing fiscal year. By direction of Supervising Surgeon-General, M.-H. S.

Respectfully yours,

PRESTON H. BAILHACHE, Surgeon M.-H.S.

ASSOCIATION NEWS.

Further Delay in Publication of Official Proceedings.

4 EAST 37, NEW YORK, June 21, 1898.

To the Editor:—Your telegram is at hand in regard to the resolutions and report of Executive Committee. I was more than half sick at Denver and could not write up the proceedings of the Executive Committee; in my book of notes there was an immense mass, and so put the book and all in my trunk to do it here at home. The trunk got separated from me and

only reached me just now, and I have been overwhelmed with accumulated work that I have not yet tackled it, but will do so at once, and send on the resolutions, etc., very shortly.

In haste, yours sincerely,

L. DUNCAN BULKLEY, M.D.

SOCIETY NEWS.

American Academy of Railway Surgeons. The next meeting of the American Academy of Railway Surgeons will be held in Chicago, Oct. 5, 6 and 7, 1898. D. C. Bryant, Secretary, Omaha, Neb.

Michigan State Board of Health. The quarter-centennial celebration of the establishment of the Michigan State Board of Health, to be held in Detroit, will include addresses by leading sanitarians of this country. It will commence August 9, at 9 A.M., and continue throughout the day, there being three sessions, morning, afternoon and evening.

The Third International Congress of Applied Chemistry, Vienna, July 28 to August 2, will discuss the international unification of the methods of analysis for tests of products whose commercial value is based on their chemie constitution; also for tests to control various chemie industries; also instruction in chemistry and numerous other subjects of general interest. Secretary, F. Ströhmer, Schonburg Strasse, No. 6.

Annual Meeting. The Annual Meeting of the White Mountains Medical Association, Connecticut Valley Medical Association, and White River Medical Association will be held at Hanover, N. H., July 29 and 30, 1898. The program includes: "Early Operation for Gall Stones," by W. H. Conant of Boston; "Racial Aspects of Disease," by Prof. C. D. Wells of Dartmouth College; "Fractures," by P. S. Conner; "Diagnosis of Pelvic Disease," by Paul F. Mundé; "Clinical Remarks on Treatment of the Eye," by David Webster, and a paper, subject unannounced, by Wm. H. Parish.

Oregon State Medical Society.—The twenty-fifth annual meeting of the Oregon State Medical Society was held in the parlors of the Imperial Hotel at Portland, June 2 and 3. The meeting was quite well attended, and the papers presented, although small in number, were of exceptionally high order. Several visitors were in attendance from outside of the State. The officers elected for the coming year were: President, C. H. Hall, Salem; secretary, William F. Amos, Portland; treasurer, Mae H. Cardwell, Portland. The next meeting will be held at Portland in June, 1899. After the close of the meeting a party of delegates from Oregon and Washington State Medical Societies left for Denver to attend the AMERICAN MEDICAL ASSOCIATION.

State and Provincial Boards of Health.—The thirteenth annual meeting of the Conference of State and Provincial Boards of Health of North America will be held in Detroit, Mich., Aug. 9, 10 and 11, 1898. The first day, August 9, will be given to meeting with the Michigan Quarter Centennial Celebration in effecting organization and hearing reports of committees; the second day to the subject: "What are the Principal Lines of Work of Your Board? How is Each Accomplished? What Modification, if any, does the Experience in Your State Suggest?" The third day will be given to discussion of the various phases relating to the restriction and prevention of tuberculosis. The phases proposed are: 1. Etiology. 2. Morbid Anatomy. 3. Statistics. 4. Identity of Tuberculosis in Man and Animals and its wide Distribution among the latter; also its Communication to Man through Food. 5. Economic Phases. 6. How may Tuberculosis be Prevented?

PUBLIC HEALTH.

Contagious Diseases.—No colonists affected with contagious diseases are allowed to settle in western Australia, according to a recent official decree.—*Sem. Méd.*, May 25.

An epidemic of measles has precipitated by a few weeks the closing of a school in the Borough of the Bronx, New York City.

The building has been fumigated, but it is not known when it may be reoccupied. The parents of over a thousand children are somewhat clamorous over the anticipated loss of educational advantages and are said to connive at the suppression of reports. The same old conflict between the individual and the State therefore still prevails.

The Complications of measles are liable to be much more serious in hospitals as the patients are exposed to contagion from streptococci which seem to acquire increased virulence in passing from one person to another. The contagiousness of measles during convalescence has been confirmed again by a number of soldiers recovering from scarlet fever, who were placed in a ward occupied by a few convalescents from measles, and all contracted measles, which suggests that disinfection is required also after this disease.—*Progrès Méd.*, May 21.

Fin de Siecle Milk.—An establishment has recently been opened at Berlin to supply "diabetes milk," made according to v. Noorden's formula: 1 per cent. sugar and 6 per cent. fat. Also Jaworski's "strength milk" for forced nutrition with passive exercise; 10 per cent. fat. But the main object is the production of milk for infants, made to correspond to mother's milk by diluting and centrifugalizing cow's milk and adding milk sugar, according to the formula of Professor Gaertner of Vienna.

Unification of the Statistics of American Cities.—A motion introduced in Congress through the Reform Club of New York authorizes the Commissioner of Labor to compile and publish annually as a part of the bulletin of his department an abstract of the main features of the official statistics of the larger cities of the country. The public are now dependent for their statistics upon local reports, which too often confuse and bewilder rather than make clear the criminal, vital and social facts they attempt to collate. The object of the present movement is to give uniformity of scope to these statistics and bring them together in one intelligent tabulation, or series of tabulations, as the commissioner's means will afford, and we trust that the Reform Club will bear in mind that this class of skilled work requires "the sinews of war" not less than the other lines of work assigned to the commissioner.

Yellow Fever.—Dr. Lacerda reiterates his assertions that it is possible and practicable to entirely eradicate yellow fever in a town by tearing down the old damp, sunless houses that are known to be foci of infection, and disinfecting those that it is impossible to destroy, as also the holds of vessels. The germs die in the sewers and in sunshine, the usual means of transmission being the air, and only in a circumscribed radius, although they can be carried in clothing, merchandise, etc. He concludes by stating that persons who have become acclimated to yellow fever may lose their immunity by an eight months' residence in a temperate climate.—*Gaz. Méd. de Bahia*, February.

Two new cases of yellow fever were reported at McHenry, Miss., June 20, a total of seventeen cases since May 20.

Insanitary Wall Papers.—The fact is of no small importance to be kept in mind that, though the unwholesome exhalations of papered walls mostly emanate from such papers as have a blue or a green ground, they also occur where the blue or green constitutes the largest part of the pattern, the dye stuff being chiefly composed of blue or green ultramarine. The latter is entirely harmless, but has the property of becoming decomposed by slightly sour liquids and diffusing a most disagreeable odor, a development of sulphuretted hydrogen during the slow process of decomposition. The paste used for fixing wall paper is frequently of a somewhat sour or readily souring character and quickly penetrates the paper, causing the above-mentioned effect, a very slight degree of fermentation sufficing to bring about the offensive result, and this appears, too, the more markedly if the walls are slightly damp and already

covered with several layers of paper so that the lime plastering can not have a neutralizing tendency on the lactic acid in the paste, etc. In such cases, therefore, where it is necessary to affix wall paper on a ground of old paper, as well as in all cases where green or blue is used, it is recommended to employ only such gluing agents as do not sour, or if inclined to decomposition, contain slight quantities of lime, milk or soda solution before use.

Typhoid Fever from Ordinary Streams.—The secretary of the State Board of Health of Michigan has issued the following warning to young men and all who bathe in streams: Recent reports to the State Board of Health show that at least two cases of typhoid fever have been caused by drinking the water in or from the Kalamazoo River. In no case should water be used for drinking or culinary purposes from a river or stream into which sewage is emptied or privies are liable to drain; and as most of the rivers and streams of this State have towns situated upon or near their banks, from which sewage is received, and privies are liable to drain, therefore it is very dangerous to use the water from any of the rivers or streams for any culinary purpose whatever, except the water be first boiled, and it should not, in any case whatever, be drunk, unless previously boiled. Cases have been reported where typhoid fever has been contracted by bathing in streams. Probably this will be most likely to occur through accidentally or carelessly taking the infected water into the mouth. Especially should no person bathe in any ordinary stream just below any city, village or other source of sewage or privy drainage.

NECROLOGY.

RICHARD CHANNING MOORE PAGE, M.D., died June 19, in Philadelphia, after about a week's illness. He was born at Keswick, Albemarle Co., Va., Jan. 2, 1841, the youngest child of Dr. Mann Page and Jane Frances Walker. After remaining in the University of Virginia until the close of the session in 1861, he entered the Confederate Army as an artillery man and served under Gen. Joseph E. Johnston and on the staff of Gen. John C. Breckinridge, where he remained until the end of the war. He was an active participant in the battles of Fredericksburg, Chancellorsville, Mine Run and Gettysburg, in the last of which he was severely wounded. Subsequent to the war he returned to the University of Virginia to study medicine, but removing to New York City in 1867, he received his medical degree from the New York University in 1868 and at once began his career in the eastern metropolis. He was indefatigable as a teacher and likewise wrote acceptably, "A Practice of Medicine," "Physical Diagnosis," "Sketch of Page's Battery," and the "Genealogy of the Page Family" being among his more important contributions. As a member of a large number of medical and historical societies he became widely known and appreciated.

JOHN S. MCGUIRE, M.D., Seattle, Wash., aged 65 years. Dr. McGuire had the honor of being one of the famous six hundred whose deeds are told in the "charge of the light brigade." He also received medallions and marks of honor for brilliant services at Inkerman in the Crimean War. In 1871 he resigned his commission in the British Army and after a short residence in Australia went to San Francisco, where he practiced for a short time. He came to Seattle in 1889, where he resided until the time of his death.

SAMUEL GRAHAM, M.D., Butler, Pa., died June 21, aged 62 years. He was a member of the class of 1862, Jefferson Medical College, and for thirty-three years one of the leading practitioners of Butler County, Pa.

EBEN JACKSON, M.D., Castleton Medical College, Vt., 1856, of Somerville, Mass., died June 22, aged 73 years. He served under Grant, and was in charge of hospitals at Memphis,

Vicksburg and elsewhere, at different times. From having participated in several battles he was known as a "fighting doctor," but at the close of the war he entered upon civil practice, in which he remained until his death.

J. B. JOHNSON, M.D., Allegheny, Pa., June 20, aged 61 years.—Calvin D. McDonald, M.D., Kansas City, Mo., June 19, aged 63 years.—W. F. Miller, M.D., Louisville, Ky., June 17, aged 74 years.—W. F. Swisher, M.D., Woodburn, Iowa, June 23.—T. N. Cunningham, M.D., Princeton, Ill., June 22, aged 54 years.—E. J. DeRaimes, M.D., New York University, 1882, died at his home, Hudson Boulevard, Union, N. J., June 18, aged 39 years.—J. A. McCoy, Tacoma, Wash., aged 71 years.—W. W. Beach, M.D., Tekoa, Wash., aged 50 years.

BOOK NOTICES.

Twentieth Century Practice. An International Encyclopedia of Modern Medical Science, by Leading Authorities of Europe and America. Edited by THOMAS L. STEDMAN, M.D., New York City. In Twenty Volumes. Volume XIV, "Infectious Diseases." New York: William Wood & Company. 1898.

This volume is devoted, as its name implies, entirely to infectious diseases, viz.: Scarlet fever, measles, German measles, chickenpox, glandular fever, whooping-cough, cholera infantum, cholera nostras, Asiatic cholera, dengue, beri-beri, miliary fever and Malta fever.

The contributors to this volume are: Dillon Brown, M.D.; David Bruce, M.B., C.M.; Sir Joseph Fayrer, Bart., M.D., LL.D., F.R.S., F.R.C.P., R.C.S.; Frederick Forchheimer, M.D.; A. Jacobi, M.D.; A. Metter, M.D.; Nathaniel Read Norton, M.D.; Joseph O'Dwyer, M.D.; Theodor Rumpf, M.D.; A. A. De Azevedo Sodre, M.D.; Dawson Williams, M.D., F.R.C.P.

The high character of the contributors prepares us for the excellent quality of the work and one is not disappointed at the result.

This volume is a fitting companion of its predecessors in this magnificent series and one to which the reader may turn for complete information on this important class of diseases.

Aphasia and other Speech Defects. By H. CHARLTON BASTIAN, M.A., M.D. New York: D. Appleton & Company, 1898.

In this work the author has reproduced with additions the Lumleian Lectures delivered before the Royal College of Physicians of London, 1897, and published in the *Lancet*. These lectures form parts of chapters 1 and 2, and nearly the whole of chapters 6, 8 and 9. Chapter 7 was the Clinical Lecture delivered at the University College Hospital, which appeared in the *Lancet* for September, 1897. With these exceptions the remaining matter is entirely new.

This author, who is well known in other biological fields, in this volume is seen at his best. Nothing unnecessary, nothing redundant, the sentences go straight to the mark with the practiced skill of the literary expert. The student wishing to acquire knowledge of this interesting disease, and the practitioner wishing to refresh his memory and gain additional knowledge, will be charmed with this work by Bastian, and as of its accuracy there is no question, we have no doubt about its reaching permanent popularity.

Modern Gynecology. A Treatise on Diseases of Women, comprising the results of the latest investigations and treatment in this branch of medical science. By CHARLES H. BUSHONG, M.D. Illustrated, second edition and enlarged, pp. 404. New York: E. B. Treat & Company. 1898.

A man who inflicts on the profession a work on gynecology at a time when our shelves are loaded with them, should either have something very new and striking, or else apologize for writing the work. The older authors usually commenced their work with an apology for having written. Careful examination of this work does not show any very particular reason for its

publication, although its statements are clear, the illustrations are good and the compilation of existing knowledge fair.

The old dosage, however, is used in the prescription writing.

Diseases of the Stomach. A text-book for practitioners and students. By MAX EINHORN, M.D., Instructor in Clinical Medicine at the New York Post-Graduate Medical School and Hospital; Visiting Physician to the German Dispensary. Second Revised Edition. 502 pages. Price, cloth, \$3.25 net; flexible leather, \$3.75 net. New York: William Wood and Company, 1898.

Members of the ASSOCIATION will remember with pleasure demonstrations of gastro-diaphany made in the ASSOCIATION meeting by the author of this work, and it may be said that since that time medical literature has been enriched by a large number of treatises on the subject. The first edition was a thorough exposé of the existing state of knowledge on the subject.

This edition is not materially altered from its predecessor, which was published late in 1896, and in our notice of that edition we took occasion to commend the work, a commendation in every way merited.

Manuali Hoepli: Spiritismo. Di ARMANDO PAPPALARDO. Milano: Ulrico Hoepli. 1898.

Magnetismo e Ipnotismo. Per il DOTT. G. BELFIORE. Milano: Ulrico Hoepli. 1898.

These are two of the more recent of the little pocket manuals issued by the Italian house of Ulrico Hoepli. The first of these discusses the phenomena of spiritualism in rather a more respectful manner than an American medical author would; the second is a discussion of the phenomena of hypnotism according to the latest European literature of the subject. Both are compilations, but such have a very useful function and will probably be serviceable to those who can read them. While spiritualism has interest only as a psychic aberration, and some of the literature of hypnotism also has in it a larger element of human credulity than is consistent with genuine science, such manuals as these are not without interest, and that on hypnotism appears to be on the whole a fair statement of verified facts.

A Manual of Instruction in the Principles of Prompt Aid to Injured, including a Chapter on Hygiene and the Drill Regulations for the Hospital Corps for the U. S. A. Designed for Military and Civil use, by ALVAH DOTY, M.D. Second Edition, New York: D. Appleton Company, pp. 302, 1898.

The second edition of this Manual presents a thorough revision and some enlargement.

A chapter on Hygiene has been introduced, and a chapter on the recently adopted Drill Regulations for the Ambulance Corps of the U. S. A. has been added. National guardsmen, railroad employes and those exposed to accident will find the book of great value.

Transactions of the American Association of Obstetricians and Gynecologists. Vol. 10, pp. 483, Philadelphia: Wm. J. Doran, 1898.

This volume includes the minutes of the meeting and the papers read at the meeting at Niagara Falls, New York, August 17, 18, 19 and 20, 1897. The exhibition of specimens presented with their illustrations occupies an important place in the work. Obituary articles on the late Traill Green, Fletcher D. Mooney and James Greig Smith of England, are included in the volume, which is only just to say surpasses its predecessors. The illustrations are finer than those usually found in volumes of transactions.

Atlas and Essentials of Pathological Anatomy. By Dr. O. BOLLINGER. Volume II. Urinary Apparatus, Sexual Organs, Nervous System and Bones. With 63 colored figures upon 52 plates and 17 illustrations in the text. Pp. 252. New York: William Wood & Co. 1898.

This excellent series of atlases has a valuable addition in this volume by Bollinger. The plates are prepared from the actual specimens and the coloring is strikingly natural. For reference this atlas is invaluable.

MISCELLANY.

The Monument to Pasteur in front of the Pantheon in Paris is now almost completed. The sculptor, M. Falguière, has added a group of a mother with her child thanking Pasteur, whom Fame is in the act of crowning with laurels. The international subscription to the memorial, according to the *British Medical Journal*, now approaches £13,000.

Anal Imperforation in a newborn infant that required an iliac anus was followed by intestinal prolapse. Kirmisson then introduced a sound through the artificial anus into the lower intestine, working it through to the perineum, and successfully re-established a normal anus. The infant, four days old, was presented at a recent meeting of the Paris Acad. de Méd.

Etiology of Pertussis.—The results of recent research by R. Behla confirm the announcement of Deichler and Kurloff that the micro-organism of this affection is not a bacterium but an ameba belonging to the protozoas, propagating by division and spore-formation. It is not found in the blood nor epithelium and does not grow inside the cells.—*Deutsche Med. Woch.*, May 12.

The Presence of an Antitoxin in the bile of animals dying from the cattle plague has been established by Koch, and now by E. I. Frantzius in regard to animals dying from rabies. The introduction of equal parts of bile and cerebral substance derived from the same rabid animal, rabbit, introduced under the dura mater of another rabbit, was not followed by any morbid manifestations, but if the bile had been taken from a non rabid animal, the rabbit promptly succumbed to rabies.—*W'ratsch*, April 18.

Reform at Bellevue Hospital.—The Commissioner of Charities of New York has decided to reorganize the staff of the chief hospital. He hopes to so select the staff that educational interests will be conserved, but he purposes to break up the "practical monopoly," as it has been called, of the great schools. Inasmuch as there will be candidates forthcoming in number sufficient to fill ten such staffs, it can well be understood that his self-assumed lot will not be a happy one for some time to come.

Iodin in the Blood.—Gley asserts that the iodine discovered by Baumann in the thyroid gland is in reality derived from the blood. His research has resulted in establishing the presence of iodine in the blood, stored in the red corpuscles, but only in adult animals.—*Semaine Méd.*, May 25.

The Latin-American Scientific Congress opened auspiciously in Buenos Ayres in April with 110 members inscribed and crowded attendance. A number of interesting and valuable communications were presented on hygienic and medical subjects by delegates from the various Latin-American countries. We note among them that cancer seems to be increasing in South America as rapidly as elsewhere. In Buenos Ayres it has risen from 91 in a thousand deaths to 115, in the last twenty-six years. The next Congress will convene at Montevideo in 1901.

Intestinal Stenosis Consecutive to Gangrene Cured by Entero-anastomosis Without Resection.—J. Schulz reports a case in which eight days after the dark blue loop of intestine had been reduced during herniotomy, symptoms of severe stenosis appeared, fecal vomiting, pain, etc. It was found that the stenosis, ten centimeters in length, involved the whole of the intestine that had been incarcerated. On account of the threatening general condition he abstained from resecting and merely performed an entero-anastomosis, which proved perfectly successful. Only two similar cases are on record.—*Garré and Maas; Münch. Med. Woch.*, May 17.

Bone Clamp and Fracture.—Parkhill (*Annals of Surgery* for May) presents a method for the fixation of the fragments in recent fractures where there is a tendency to displacement, and

ununited fractures after resection, and in fractures with mal-union after resection, with reports of a number of cases. He claims for his instrument that union has been secured in every case in which it has been used; that it is easily and accurately adjusted; that it prevents both longitudinal and lateral motion between the fragments, and that the presence of the shafts in the bone stimulates the production of osseous tissue; that nothing is left in the tissue to reduce their vitality or cause pain and infection, and no secondary operation is necessitated.

Mr. David H. King Jr. of New York, has offered to the Red Cross relief committee his house at Jekyl Island, S. C., for use as a hospital. Judging from the newspaper illustrations, the surroundings are unexceptional and the residence itself already built on the pavilion plan. Jekyl Island is within an hour's travel of Fernandina, Fla., and its healthfulness and location make it an ideal site for an army hospital. Soldiers becoming ill at the camp which, it is reported, will be established at Fernandina, can be easily taken to this island. It is also conveniently situated for the care of soldiers wounded on Cuban battlefields. Not only will Mr. King give the use of the house for hospital purposes, but he will maintain it as well.

The New York Post-Graduate Hospital.—In the case of Dr. Charles B. Kelsey, who was removed from a professorship in the New York Post-Graduate Hospital by a majority vote of the Board of Directors of that institution, the appellate division of the supreme court has reversed the decision of the special term directing his reinstatement. The higher court holds that the Board has power to remove a member of the faculty by a simple majority vote, in cases where no charge of misconduct was made, but that a vote of three-fourths was necessary to effect a removal upon charges. In the first instance, the power is declared to be absolute, and in the second it is judicial. "It seems reasonable," says Mr. Justice Marrett, "that a majority vote should have been deemed sufficient for a removal at pleasure, while a three-fourths vote should have been required for a removal upon charges. When a professor is removed at pleasure, no stigma attaches to the act of removal. His services are no longer required and he is told so. That is what, in substance, such a removal amounts to."

Stagnation of Stomach Contents.—Benedict (*Medicine*, May) in discussion of this subject includes the following diseases: Atony, slight dilatation (the usual condition in cases called gastroptosis), true dilatation due to essential weakness and stenotic dilatation, from cancer, ulcer, fibroma, or external pressure involving the pylorus. Hour-glass contraction may fall either under the second or third. Stenotic dilatation is most frequently found with pyloric cancer and next with cicatrizing ulcer at the pylorus, or it may be first ulcerative and then malignant. Malignant diseases may sometimes have no obstructive bearing on the dilatation.

Glossitis in Typhoid Fever.—In the *Johns Hopkins Hospital Bulletin* for May, McCrea reports a case of glossitis complicating typhoid fever, which occurred in the Johns Hopkins Hospital, the first such case in over seven hundred cases of typhoid fever there. He considers it of especial interest in that it occurred during convalescence from the original attack and ushered in a relapse, being apparently the first symptoms of the relapse after twenty-four days of normal temperature. The relapse itself was mild except for the severe onset, and no further trouble in swallowing affected the patient after subsidence of the swelling. Diminution of the swelling in the left half of the tongue followed after the removal of the blood for cultures, and he considers this a support of the value of free incisions into the tongue in severe cases.

Motor Neuron.—In *Medicine* for May, Patrick of Chicago writes on "Motor Neurons in Practical Diseases." He finds that, "A lesion of any part of the lower motor neurons causes

paralysis, flaccidity, atrophy, loss of the deep reflexes, and reaction of degeneration. A lesion of any part of the upper motor neurons causes paralysis, spasticity, no atrophy, exaggeration of the deep reflexes and no change in the electric reactions."

Professor Senn to go to the Front.—It is announced in army medical circles that the regular troops of the Fifth Army Corps will shortly have the benefit of the professional services of Col. Nicholas Senn. Since his appointment and muster Colonel Senn has been at Chickamauga, organizing the medical department of one of the army corps there stationed; but it is considered that his services could be employed to much greater advantage in the field hospitals near Santiago, Cuba. It is probable that he will be assigned to special duty with General Shafter's command. The chief surgeon of the corps is Lieut.-Col. Benjamin F. Pope, United States Volunteers.

Movements of Medical Officers.—Captain John L. Phillips, Assistant Surgeon U. S. Army, just returned from the Pacific Coast, has been assigned to the 2d Army Corps at Camp Alger, Virginia; Acting Assistant Surgeon, Medwin Leale, has been placed on duty with the cavalry squadron at headquarters of the Corps, and Assistant-Surgeon Whitmore Steele, 8th N. Y., has resigned on account of physical disability. Three medical officers have been sent to the 3d Corps at Chickamauga, Ga.; Captain Chas. B. Ewing, U. S. A., from Tampa, Fla., Captain Adrian S. Polhemus from Fort Wingate, New Mexico, and Captain John S. Kulp from his late station on the Pacific Coast. Two officers have been ordered to report to General Fitzhugh Lee, commanding the 7th Army Corps at Jacksonville, Fla.; Captains Paul Clendenin and Henry S. T. Harris. Changes at the hospitals are: Captain H. A. Shaw, U. S. A., from the general hospital at Key West to Key West barracks, Fla.; Captain R. S. Woodson, U. S. A., from the ambulance train at Tampa, Fla., to the hospital at Fort McPherson, Ga., and Acting Assistant Surgeon, John R. Devereux of Washington, D. C., to the Leister Hospital at Chickamauga, Ga.

Medical Appointments Confirmed.—Dr. L. L. Seaman of New York to be Surgeon of the 1st Regiment of Engineers. Dr. Seaton Norman of the U. S. Marine-Hospital Service to be Surgeon of the 3d Regiment of Volunteer Infantry. Drs. John W. Cox and Zachary D. Massey of Tennessee to be Assistant Surgeons of the 6th Regiment of Volunteer Infantry. Drs. M. Landry of Louisiana and R. T. Burr of California to be Assistant Surgeons of the 7th Regiment of Volunteer Infantry. Dr. James H. Hepburn of the District of Columbia to be Surgeon of the 8th Regiment of Volunteer Infantry. Dr. A. Pallones of New Jersey to be Surgeon of the 9th Regiment of Volunteer Infantry. Dr. Wm. M. Fuqua of Kentucky to be Surgeon of the 10th Regiment of Volunteer Infantry.

An Army Hospital on Wheels.—Major Charles Richard, Surgeon U. S. Army, has been in Washington, D. C., recently superintending the outfitting of the R. R. Hospital train to the command of which he has been assigned. The train left for Tampa, Fla., June 17, by way of the Southern Railway to Columbia, South Carolina, and over the Florida Central and Peninsular to its present field of duty. It consists of ten Pullman sleeping coaches, a dining car, a cooking car and a combination coach, and is well equipped with such medical and surgical supplies and apparatus as would be likely to be of use while on the road with sick and wounded. Major Richard is assisted by Captain H. R. Stiles, Assistant Surgeon U. S. Army, with two hospital stewards, three cooks and twenty-two nurses of the hospital corps of the army. From time to time as may be required a section or the whole of the train will return with sick and wounded, who will be conveyed to one or other of the army general hospitals; and when not en route the train will be used as a receiving general hospital at the port of connection with Cuba. Ambulant hospitals of this kind were in

use during the last eighteen months of the Civil War. In 1864, when General Sherman was at Atlanta, Ga., three trains ran regularly between that place and Louisville, Ky., a distance of 472 miles.

Surgeon General Sternberg on the Danger from Yellow Fever.—In a letter to the *Army and Navy Journal*, Surgeon-General Sternberg expresses his views of what would happen if we should send an army to occupy any of the infected Cuban ports during the unhealthy months. He says:

In your issue of April 23, page 642, the statement is made that Gen. Sternberg "expresses confidence in the excellent sanitary provisions of the military service and does not fear that yellow fever will prove more harmful to the troops than diseases which are common in the northern latitudes," etc. I have not expressed any such optimistic opinion, and regret to say that it is not justified either by my studies relating to yellow fever or by my personal experience. History teaches that when a considerable number of unprotected persons are exposed in a yellow fever infected locality during the months when this disease is most prevalent (May 1 to November 1, in the latitude of Havana), an epidemic almost infallibly results. In the last week in April of last year, there were seventeen deaths and seventy new cases of yellow fever in the city of Havana. Now, suppose that we had a similar number of cases at the same season in New Orleans and that 20,000 strangers from the North should go there to spend the summer, what would be the result? All past experience supports the belief that a majority of them would have yellow fever, and that from 20 to 40 per cent. of those taken sick would die. This is what I anticipate would happen if we should send an army to occupy Havana, or any other infected seaport on the coast of Cuba during the summer months. If, however, these troops could be camped upon high land in the interior, and circumstances were such as to enable them to comply with all of the exactions of modern sanitary science, I am of the opinion that our loss from yellow fever would not be serious. But in time of war military commanders are expected to take their troops to the points occupied by the enemy, and a picnic in the interior with frequent changes of camp, etc., is perhaps not exactly what we may expect. I am not an alarmist, but I believe in looking facts fairly in the face, and can not allow your statement of my opinion to have currency at such an important moment in our country's history without a protest.

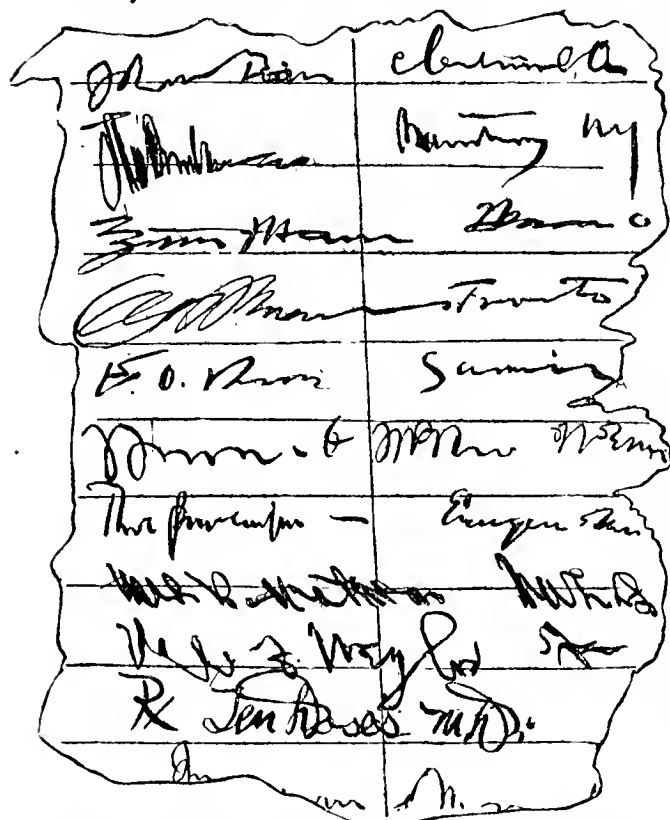

Transient Agrypic Delirium is the term proposed by Agostini for the psychosis observed after prolonged insomnia. He cites a couple of serious cases, both recovering after a couple of days sleep, and describes experiments with two healthy dogs kept awake for two and three weeks. The central nervous system showed the same histologic alterations as after intoxication with arsenic, lead, alcohol, etc., and he assumes that in the same way psychoses such as mania, lypemania and mental confusion, hitherto considered essential morbid forms, *sine materia*, are frequently of autotoxic origin, the result of lesions of the nerve cells produced by the action of the autochthonous poisons of the organism. —*Semaine Méd.*, May 14.

X-Rays in Medicine. Williams (*Medical News*, May 14) says that in making the diagnosis, "Physicians will find that although much that the X-ray reveals can be recognized by other means it would often be an advantage to have this information confirmed by another method, and we must also appreciate that it can extend our knowledge into a field which was previously beyond our reach." By the X-ray alone, in certain cases, aneurysm, emphysema and pneumothorax, diagnosis may be made, but as a rule it is only one method and should be used only in connection with others. In suitable cases the X-ray gives earlier evidence of disease than the older methods. He finds it indispensable in making a complete examination in diseases of the chest where they completely change the diagnosis previously made.

Widal Test.—Blackburn (*Medical News*, May 7) makes a report concerning this test in typhoid fever from data obtained during his service in the Presbyterian Hospital in Philadelphia, May to October, inclusive, 1897. In all suspected cases of typhoid fever, the blood was subjected to this test, and a specimen was taken immediately on admission of the

patient to the hospital, the object being to find the first day of the disease on which the test was positive. In eighty cases of enteric fever, as established by the clinical course, the test was positive except in two. In one case of catarrhal fever the test was, on the seventh and ninth days negative, eleventh and thirteenth days doubtful, and positive on the fourteenth day. In one case of uremia positive reactions were secured twice. This patient had had typhoid fever five years before. In one case of catarrhal, having had typhoid three years before, there was a positive reaction. He concludes that it is a good corroborative test; in doubtful cases early in the disease it does not assist in diagnosis, and that in severe cases test is positive early, yet in a few typic cases it appeared to be negative.

Why Prescriptions Go Wrong.—Here is a squib from one of the New York City evening papers, one of the saffron-colored variety of which you have heard:

"This cut represents a page from a Denver hotel register at the time of a recent national convention of physicians. It shows why drug clerks make mistakes in prescriptions."

A Research on Precocious Gestation.—Dr. Sage of Bordeaux recently delivered by means of forceps, a girl aged 13 years and six months, of a male child at term weighing eight and a half pounds. The mother seems to have become pregnant a month after her first menstrual period. There was nothing abnormal regarding the puerperium. This has led Dr. Sage to look up the subject of early pregnancies, which are less common in France than in other European countries. He has been unable to find any mention of a case occurring at so early an age as his own in recent medical literature, the earliest being at the age of 14 years and one month. In a medical dictionary published in 1823 mention is made of girls having been received into the Paris lying-in hospitals at 13 years of age, and during the Revolution at 11 years, and even before that age. The earliest cases recorded in other countries are Molitor's case in Luxemburg, where a child aged eight years and three months, became pregnant and was delivered of a mole containing a dead fetus seven months afterwards (this

was in 1877); Outrepont's case (1825) of a German girl, aged 9, who aborted in her fourth month; Haller's case in Switzerland of a girl born in 1751 and delivered in 1759, and Dodds case in England (1881), where a Yorkshire girl, aged nine years and eight months, was delivered of a living child at term. Here the young mother had menstruated from twelve months of age.—*Lancet*, April 23.

Cost of the Hospital Ships.—The Government has paid more than \$1,000,000 for the two hospital ships, the *Solace* and the *Relief*, \$450,000 being to the Maine Steamship Co. for the *John Englis*, renamed the *Relief*. The price paid to the Cromwell Line for the *Creole*, now the *Solace*, was \$600,000, making a total of \$1,050,000 for the two hospital vessels. The estimated cost to the War Department for fitting up the *Relief* is \$50,000 in addition to many things which are to be presented by various organizations which are working to aid in reducing the horrors of war as much as possible. An army officer said that about twice as much had been expended in fitting up the *Solace*, as the Navy Department had a special appropriation for the purpose and also greater facilities for doing work upon ships, as it controlled the navy yards. The total expense of procuring and equipping the two vessels will not be far from \$1,250,000. This amount would be increased 50 per cent. if a third vessel should be purchased and equipped, as would be necessary if an expedition was sent to Porto Rico. "It would bankrupt the Department," said an army surgeon yesterday, to get another hospital ship; but one will be needed for any additional expedition. The English Government sends a hospital ship with every military expedition. We have never had to send one beyond the confines of our own country, but in the Civil War transports were used to convey the wounded to points from which they could be readily transferred to hospitals on land. There has been a noble response to the request for gifts to fit up the hospital ship with all that can be put aboard to aid the work of the surgeons and nurses. We hope to have the vessel fully equipped and ready for us in five weeks from the time she was turned over to the Government, but it will depend on the speed of the contractors. The most important things are being done first, so that if a sudden emergency arises the vessel can answer a call for its services. The staff of physicians has been engaged, there have been six female and ten male trained nurses secured, while from the hospital corps of the army men have been secured who will do the heavy work of lifting patients and attending to the wards, while they will be trained in nursing, so as to relieve the regular staff and assist when the vessel has many patients. We may get orders any day to start as soon as possible, and everything is being made ready."—*N. Y. Tribune*, June 20.

The War Revenue Law.— . . . The new law requires that every medicinal preparation shall be subject to the stamp tax, excepting: 1. Physicians' prescription medicines. 2. Extemporaneous preparations put up "for any person" by a retail druggist. 3. Uncompounded drugs or chemicals. 4. Non-proprietary preparations which are not put up "in style or manner similar to that of proprietary medicine in general," which is presumably intended to mean galenic preparations which bear on their labels only their official names and nothing concerning their properties, uses or any claims to superior virtue. The preparations specifically included, according to the evident meaning of the act, comprise: 1. All medicinal articles having a trade-marked name, or in which proprietary rights are claimed. 2. All medicines compounded according to a secret formula. 3. All medicines advertised on their labels or otherwise as remedies or specifics for any ailment, which includes all ready-made preparations of the retail druggist, all the "non-secrets" and all "patent" medicines. 4. All preparations of whatsoever nature which are put up in style or manner similar to that of a proprietary medicine. In brief, the act subjects to tax ready-made preparations of whatsoever description, excepting those only in which no proprietary right is claimed and which bear on their labels simply their recognized descriptive names. The act is in some particulars very

loosely phrased, and will give rise to much misunderstanding and litigation. What, for instance, is the "style or manner of a proprietary medicine" package? Are phenacetin, antipyrin and the myriad other German chemicals subject to tax? It is true they are vended "under letters patent and trade mark," but the special proviso in Section 20 declares that "no stamp tax shall be imposed upon any un compounded medicinal drug or chemical." These German chemicals are "uncompounded" and, it would seem, therefore are made the subjects of specific exemption. Should the internal revenue office so rule and these products of all others escape taxation, the tide of protest would indeed be loud and deep. The law took effect July 1. By special provision, goods in retailers' stock on that date will not be subject to tax, but will require stamps only as they are actually sold. . . . No reason can be given for taxing non-secret medicines which does not equally apply to non-secret foods and other merchandise. No reason can be given for taxing non-proprietary medicines that does not as forcibly apply to other non-proprietary products. Why then this discrimination against druggists' merchandise and the drug store? . . . Many reputable manufacturers are carefully canvassing the situation with a view to bearing their fair share of these war taxes. The profit margin in numerous products is too small to justify the retention of present prices. The intelligent pharmacist will know how and when to discriminate between a justifiable and reasonable advance and an arbitrary and extortionate demand for further tribute. In the former class are few products adapted for manufacture in the retailer's laboratory; it is in the latter class where the injustice will quite invariably be found and where the remedy is at hand.—*Western Druggist*.

Wax in the Tubercle Bacillus.—Aronson has been experimenting with large quantities of bacilli grown on glycerin bouillon and also on Proskauer's mineral medium. He found that treating 300 grams of the bacilli with ether and alcohol resulted in securing a brown tenacious substance, representing about one-fourth of the original mass, assumed by Klebs and others to be fat. Closer chemic analysis, however, has proven that this substance only contains 17 per cent. of free fatty acids, while the rest is true wax, which stains with carbol-fuchsin. The wax is also found in diphtheria bacilli, but not more than 3 to 5 per cent. of the total bulk, and it is not affected by the fuchsin in the same way. After the wax is extracted from the tubercle bacilli, if they are treated with 1 to 50 sodium, and compressed at a temperature of 130 degrees C. according to Behring's method, a very powerful toxin results. It can also be obtained without the heating, but in smaller amounts.—*Berlin med. Gesellsch.*, Session of May 11.

Colleges.

HAMLIN UNIVERSITY, Minnesota, graduated a class of twelve from the medical department June 9.—The graduating class of Harvey Medical College, Chicago, at the annual commencement held June 15 numbered eighteen.—At the annual commencement of the University College of Medicine, Virginia, there were forty-nine graduates in medicine.—Beginning with the next school year the Medical College of Niagara University will be consolidated with that of the University of Buffalo, N. Y.

Hospitals.

THE JAMAICA EMERGENCY HOSPITAL ASSOCIATION, New York City, dedicated the new hospital building on June 18.—The Lackawanna (Pa.) Hospital has received \$950 from the estate of William T. Smith.—The new wing of the Cook County Hospital, Chicago, a three-story brick structure was opened for use June 20.

Philadelphia.

PHILADELPHIA HOSPITAL OVERCROWDED.—From time to time it has been suggested that it would be best to separate the almshouse from the hospital department of this institution, but up to the present time nothing has been done and the patients keep the managers busy providing the necessary room. The Mayor of the city has suggested consolidation of all the poor districts in the county of Philadelphia and placing them under the care of the Department of Charities and Correction. Further, that while the almshouse is at present overcrowded some of the district poorhouses in the suburban sections of the city have comparatively few inmates and therefore could be used to advantage in caring for some of the patients now at Blockley. It seems that the insane department is most pressed for room and that while 1050 cases are being cared for, the facilities are entirely insufficient. Since all of the State institutions are taxed to their utmost with these unfortunates, they can not be removed from this city and the question regarding their final disposition is still an open one.

PTOMAIN POISONING.—In previous issue of the JOURNAL, notice has been taken of several cases occurring in Philadelphia. During the week just passed two households consisting of nine persons have also been poisoned in this manner. The first cases resulted from eating pork, the second from oysters, and it is now recorded that ham is responsible for the illness of these latter cases. In the early part of the week these all partook of boneless ham which seemed fresh, but within a few hours all became ill and suffered with intense pain in the abdominal region and accompanied by nausea and vomiting. A physician called in pronounced it ptomain poisoning. A day or two later another family bought ham from the same grocer and after the two elder sons had eaten of it for lunch they were shortly afterward likewise afflicted. The following morning two daughters and a younger son ate of the ham and were shortly afterward seized with similar symptoms. The attending physician pronounced the cases ptomain poisoning. All the cases terminated favorably.

BAD WATER.—After weary months of incessant toil, after constant vigilance by the physicians of Philadelphia and after the worst epidemic of typhoid fever possibly ever known here the City Council has been forced to pass the "Loan Bill" which was voted by the people a year or two ago. Much praise should be given to those who entered personally into the fight and brought to light the underhand dickerings of the councilmen. Dr. William Pepper and Dr. John K. Mitchell were among the most earnest workers along this line. Of the \$11,200,000 which will now be expended in greater Philadelphia, several million dollars will be spent in erecting and maintaining a proper filtration system. It is also gratifying to know that a large portion of this amount will be spent in the equipment of a large museum and also that the condition of the health of the people will be further improved by the construction of better streets and sewage systems.

FOR FREE CUBA.—In the death of Dr. John Blair Gibbs, who fell at his post of duty in Guantanamo, the University of Pennsylvania loses a worthy son and the United States Army a valuable assistant. Dr. Gibbs was graduated at the head of his class in this institution in 1881, and for several years made this city his home. Some time afterward he moved to New York and entered the Bellevue Hospital, serving on the resident staff. Subsequently he matriculated at the College of Physicians and Surgeons, N. Y., and was graduated in 1882. When the first call to arms was sounded he responded and is the first army surgeon to sacrifice his life for free Cuba.

WEATHER IN PHILADELPHIA.—There were three deaths and four prostrations as the result of the intense heat for the week ending July 18. In several cases the patient had suffered with heart trouble and the effects of the heat acted more remotely. Later the weather has become more pleasant and enteritis and cholera infantum has not been manifested to a very great degree.

THE PUBLIC SERVICE.

Appointments, Assignments, etc., of Medical Officers.—To the 1st Corps at Chickamauga, Ga.: Capt. Henry P. Birmingham, U. S. A. To the 2d Corps at Camp Alger, Falls Church, Va., as brigade surgeons: Major Wm. H. Devine, U. S. Vols., to report to Major General Graham, brigade not specified; Major Peter D. McNaughton, U. S. Vols., to report to General Duffield; Major George W. Grille, U. S. Vols., to the 2d brigade, 1st division. To the 3d Corps at Chickamauga, Ga.: Capt. Eugene L. Swift, U. S. A. To the 4th Corps, General J. J. Coppinger, at Tampa, Fla.: Major W. Fitzhugh Carter and Capt. J. R. Egan, U. S. A. To the 7th Corps, General Fitzhugh Lee, at Tampa, Fla.: Major Geo. T. Vaughan, U. S. Vols., brigade surgeon, and Capt. Jefferson R. Keen, U. S. A. To the Philippine expedition: Lieutenant Franklin M. Kemp, U. S. A.; Acting Asst. Surgeons C. F. de Mey from Louisville, Ky., and A. E. Halstead from Chicago, Ill. To the Letter Hospital: Major John W. Bayne, U. S. Vols., brigade surgeon, and Acting Asst. Surgeon Edwin P. Hayward. To the general hospital at Ft. McPherson, Atlanta, Ga.: Capt. Chas. E. B. Flagg, U. S. A.; the order sending Capt. R. S. Woodson, U. S. A., to this hospital was revoked. To the hospital train under Major Charles Prichard, U. S. A.: Capt. H. K. Stiles, U. S. A. From the hospital ship *Relief* to Ft. Sherman, N. Y.: Acting Asst. Surgeon Thomas A. Smith. From Washington Bks., D. C., to San Francisco, Cal., accompanying a battalion of artillery: Acting Asst. Surgeon S. Melville Waterhouse, returning thereafter to his station.

Resignations.—Major G. Frank Lydston, 2d Illinois Vol. Infantry. **Nominations.**—1st Vol. Infantry: Wm. F. Starley of Texas as Surgeon and Henry A. Ingalls of Texas as Asst. Surgeon. 3d Vol. Infantry: James A. Toole of Georgia, as Asst. Surgeon. 9th Vol. Infantry: James Mitchell of Pennsylvania and Joseph T. Scott of Louisiana, as Asst. Surgeons. 10th Vol. Infantry: Thomas McCormick Lippitt of Virginia, as Asst. Surgeon.

Nominations confirmed.—Dr. Edward Martin of Pennsylvania and Dr. Ernest Taylor Tappey of Michigan, to be brigade surgeons with the rank of Major. Wm. F. Starley of Texas to be Surgeon, Henry A. Ingalls of Texas and James Greenup Boyd of Texas, to be Asst. Surgeons of the 1st Regiment of Volunteer Infantry. Joseph A. Guinn of Georgia, to be Asst. Surgeon of the 3d Regiment. Frank P. Robinson of Tennessee, to be Surgeon of the 8th Regiment. John F. Dunshire of Louisiana, to be Asst. Surgeon of the 9th Regiment; and George N. Stoney of Georgia and John C. Dysart of Texas, to be Asst. Surgeons of the 10th Regiment.

An Inspection of the Army Medical Department in the Field.—Colonel Charles R. Greenleaf, chief surgeon of the army in the field, has recently returned to headquarters in Washington, D. C., from an inspection of the medical department in the camps at Chickamauga, Ga., and other points. He expresses himself as well satisfied with the progress made under the many difficulties with which chief surgeons had to contend. He found the health of the troops to be remarkably good, the aggregate percentage of sick to the effective force being less than 1 per cent. In General Lee's command and only a trifle over 2 per cent. at Tampa, Fla., and Mobile, Ala. It is probably about the same at Chickamauga, Ga., and Falls Church, Va., although absolute figures could not be obtained at these places because of the inability of corps surgeons to obtain records from regimental medical officers. From an examination of regimental books, Colonel Greenleaf satisfied himself that the rate of sickness was not much greater than in regular army commands. The diseases were generally those of the digestive apparatus, due to change of habits and unavoidable errors of diet and cooking incident to this early stage of the field service. There were also a few cases of pneumonia and typhoid fever, measles and mumps. Infectious cases were promptly isolated and measures were taken to prevent the spread of the disease. The advantage of caring for those who are seriously ill in general hospitals rather than in the field hospitals, is very manifest. The Surgeon-General has established general hospitals at the McPherson Barracks, Atlanta, Ga., to receive the sick from Tampa, Mobile and Chickamauga, and at Fort Myer, Va., for the care of serious cases from Camp Alger, Falls Church, Va. In addition to these there is the Leiter Hospital, capable of accommodating 400 or 500 patients, adjacent to the grounds at Chickamauga. The transfer of sick between the camps on the southern coast and these hospitals is effected by the hospital train of ten tourist sleepers, one dining and one dispensary car, Major Charles Richard, U. S. Army, in charge.

Mounts for the Hospital Corps.—An order issued from Headquarters of the Army, June 22, 1898, specifies the allowance of horses for mounts, wheel transportation, tentage, etc., for the Medical Department of the Army in the field:

	Hospital stewards.	Acting hospital stewards.	Privates.
To each regiment of infantry.	1	1
To each artillery battalion (3 light batteries).	3	1
To each cavalry regiment.	1	2
To each corps headquarters.	1	2
To each division headquarters.	1	1
To each brigade headquarters.	1	1
To each division ambulance company.	7	3	12
To each corps reserve ambulance company.	7	3	12
To each division field hospital.	2	2	6
To each corps reserve hospital.	2	2	6

Wheel transportation.—One ambulance to 400 men of the effective force. One 4-horse wagon to 600 men of the effective force. One 4-horse wagon to each brigade.

Tentage.—For each ambulance company: 17 common tents for privates; 2 common tents for noncommissioned officers. For each division field hospital: 15 common tents for privates; 2 common tents for noncommissioned officers; 1 common tent for supplies. Hospital tents on a basis of 6 patients (beds) to each tent. Hand litters, with slings, to be furnished by the Quartermaster's Department: 1 for each company; 2 for each ambulance.

Regimental Bands as an Ambulance Corps.—The Assistant Adjutant General, U. S. forces, has issued orders to the following effect, that all members of regimental bands will be instructed in hospital drill and as much of first aid to the injured as is practicable under existing circumstances. To this end all musicians will hereafter report to a medical officer attached to the regiment to which the band belongs for one hour each day for instructions until they are pronounced qualified by the medical officer who instructs them. This arrangement will add largely to the numerical force and efficiency of first-aid bearers upon the battlefield. Men will be needed who know how to handle a wounded man so as to place him with care and expedition upon a litter and transport him smoothly and without jolt to the first dressing station or to the ambulance. Practically, therefore, the instruction that band members are receiving consists of exercises in the manual of the litter, viz., marching with the litter, as litter squads composing a detachment so as to mobilize at a given point; searching for the wounded by scattering the several squads under charge of their respective squad leaders; the proper loading of the litters with the wounded, and their easy convey to some designated spot, and the placing of the loaded litters in ambulances.

The Outfit of an U. S. Infantryman in active service consists of the following: Two blankets, 10 pounds; one rubber poncho, 2 pounds; one-half shelter tent, 2 pounds; one overcoat, 6 pounds; one pair shoes, 2 pounds; one cake soap, 3.5 ounces; one pair trousers, 3 pounds; one shirt, 1 pound; one shirt, 1 pound; one pair drawers, 14.54 ounces; one pair socks, 3.45 ounces; one towel, 24 ounces; one blanket bag, 2 pounds; haversack and rations, 9 pounds; rifle, bayonet, field belt, scabbard, 12.5 pounds; canteen filled and cup, 4.5 pounds; ammunition, 100 rounds, 6 pounds; total, 64.5 pounds. This does not include the weight of the clothing and incidentals, as pocket-knife, pipe, tobacco, money, etc., which would make the total nearer seventy pounds. But by a recent order from provisional headquarters, at Chickamauga, the men in the ranks are to be somewhat relieved. The knapsack, tent, blanket, overcoat, canvas suit, change of underclothing, soap and towels are to be carried on a wagon, two of which will be furnished to each company. This will leave some forty-seven pounds, enough of a burden under the tropical sun, where every pound pulls down with double the force of its actual weight.

Army Changes. Official List of Changes in the Stations and duties of officers serving in the Medical Department, U. S. Army, from June 18 to 24, 1898.

Major Junius S. Powell, Surgeon, will proceed from Ft. Riley, Kan., to Mobile, Ala., and report in person to Brigadier General William C. Oates, U. S. Vols., Fourth Army Corps, for duty as chief surgeon on his staff.

Acting Asst. Surgeon Wylie G. Woodruff, U. S. A., will proceed from Lawrence to Ft. Riley, Kan., and report in person to the commanding officer of that post for duty.

Acting Asst. Surgeon John R. Devereux, U. S. A., will proceed from Washington, D. C., to Chickamauga, Ga., and report to Major E. C. Carter, brigade surgeon U. S. Vols., in charge of Leiter general hospital, for duty.

Capt. Jefferson K. Kean, Asst. Surgeon U. S. A., ordered to Jacksonville, Fla., to report to Major General Fitzhugh Lee, U. S. Vols., commanding Seventh Army Corps, for duty.

Capt. Peter R. Egan, Asst. Surgeon U. S. A., ordered to Tampa, Fla., to report to Major General John J. Coppinger, U. S. Vols., commanding Fourth Army Corps.

Capt. Henry R. Stiles, Asst. Surgeon T. S. A., having reported in person to the Surgeon-General of the Army, will report in person to Major Charles Richard, surgeon in charge of hospital train, for duty.

Capt. John S. Kulp, Asst. Surgeon U. S. A., ordered to Camp George H. Thomas, Chickamauga National Park, Ga., and will report to Major General James F. Wade, U. S. Vols., commanding Third Army Corps, for duty.

Major Charles Richard, Surgeon U. S. A., having reported in person to the Surgeon-General of the Army is assigned to duty in charge of the hospital train.

A board of officers to consist of Col. Charles C. Byrne, Asst. Surgeon-General; Major James P. Kimmall, Surgeon, and Major John D. Hall, Surgeon, is appointed to meet at Governor's Island, New York City, for the examination of such officers of the Medical Department as may be ordered before it, to determine their fitness for promotion.

Capt. William C. Gorgas, Asst. Surgeon, ordered to report to the president of the examining board, New York City, for examination for promotion.

CHANGE OF ADDRESS.

Adams, S. S., from Washington, D. C., to Mt. Lake Park, Md.
Bannister, H. M., from Oak Park to Evanston, Ill.
Bubna, C. W., from 190 Croton St. to 667 Quincy, Cleveland, Ohio.
Crudup, C. P., from Omaha, Neb., to Ryan, Ind. Ter.
Campbell, C. H., from Clarks to Osceola, Neb.
Chapman, W. S., from Gluch, Colo., to San Carlos, Ariz. Ter.
Chamberlin, W. A., from Rochester to Waseca, Minn.
Frost, C. A., from Chicago, Ill., to Almond, Wis.
Hilliard, W., from California Bldg. to Box 742, Denver, Colo.
Hertel, L. L., from 233 22nd to 2212 Dearborn St., Chicago, Ill.
Isham, I. D., from 2441 Washburn Ave. to Chicago Beach Hotel, Chicago.
Jackson, E., from Philadelphia, Pa., to McPhee Bldg., Denver, Colo.
Lundgren, C. E., from 455 Pacific St. to 58 Norman Ave., Brooklyn, N. Y.
Martin, A. R., from 467 Milwaukee to 732 N. Hoyne Ave., Chicago, Ill.
Reamy, T. A., from Cincinnati to Stockton, Ohio.
Storie, J. G., from Shell Creek, Tenn., to Elk Park, N. C.
Searles, L. M., from Omaha, Neb., to Box 423, Kansas City, Mo.
Shattuck E. C., from 35 Myrtle St. to 614 Tremont St., Boston, Mass.
Wagner, T. H., from Chicago to Silver Cross Hospital, Joliet, Ill.
Wray, W. E., from Wanpan, Wis., to Jacksonville, Fla.
Weaver, T. A., from Dayton, to Blachleyville, Ohio.

The Journal of the American Medical Association

VOL. XXXI.

CHICAGO, ILLINOIS, JULY 9, 1898.

No. 2.

ADDRESS.

ADDRESS OF CHAIRMAN.

Delivered before the Section on the Practice of Medicine, at the
Forty-ninth Annual Meeting of the American Medical
Association, held at Denver, Colo., June 7-10, 1898.

BY SAMUEL A. FISK, M.D.

DENVER, COLO.

It affords me peculiar pleasure to extend to you a welcome to Denver and Colorado. Having come to Colorado myself, some eighteen years ago, severely afflicted with acute pulmonary tuberculosis, which was thought to be of a fatal nature, my professional life has been almost entirely in Denver, and I have looked upon this meeting of the AMERICAN MEDICAL ASSOCIATION as one of the best ways of informing the profession of this country of what the climate of Colorado is and what it can accomplish, and so of repaying, to a slight degree, some of my obligations to this State, and of making thousands of others sharers with me in the benefits that climate can offer. I am fully aware that the Colorado climate is not always uniform; that frequently, like a pretty girl, she pouts; and that too, at times when one would like to have her at her best. But taking her for all in all, the climate is unsurpassed, and favorable results, so far as pulmonary disease is concerned, can be seen on every hand, and recoveries are to be numbered by the tens of thousands, which is the best proof of the efficacy of the Colorado climate in such disease.

The welfare of the AMERICAN MEDICAL ASSOCIATION especially demands our attention. Starting as she does on a fresh half-century of work, we who are interested in her well-being have every reason to look for a greatly enlarged field of usefulness and of influence. The good of the ASSOCIATION as a whole is closely allied with the good of each individual Section; and in connection with the work that has devolved upon me during the past year, with reference to the Section on the Practice of Medicine, a few things have suggested themselves which I wish to call to your attention.

I have found that the time of meeting conflicts with the work of many of the profession engaged in medical education, their final examinations and graduations coming at this time. To me, this is a matter of serious consideration, as in the present instance it has robbed us of the presence of a number of men prominent in medicine, and whose assistance is certainly to be desired. If the ASSOCIATION is to be a National one, and not confined to the narrow limits of the East, it seems to me that this subject will need adaptation. To me, it is to be deplored that the old discussion on the ethics deprives us of the assistance of still another set of men, whose co-operation would be valuable. As some effort is now being made to bridge over the old rupture, I wish to express the hope that we may, ere long, reclaim those who left on this score, and I wish

to urge that, on our part, we do not require too great exactions. Still another party stands aloof from a feeling of disgust at what they call the "politics" of the ASSOCIATION. It may be that they place too great stress upon this one point, yet it does seem to me as though we should make every effort to have our ASSOCIATION known as a scientific rather than a political body.

The man practicing medicine exclusively, is frequently hampered by the professional brother on the one hand, who demands that he shall put the hand into the side and have a demonstration to his senses; and, on the other, of the laboratory man, who demands that the clinical results shall tally with those of mechanical appliances. As was ably pointed out by Prof. F. C. Shattuck in his official address before a State society a year or so ago, "Internal Medicine" should use these different results, rather than be used by them. Even now, having been thoroughly scared, she is again resuming courage and great things are to be hoped for in the future. It may be that she, herself, is somewhat to blame for these conditions and that many a fault has been allowed to be covered up by a theory rather than a fact. "The peculiar type of disease," it seems to me, is often used as a cloak for one's short-comings, or where this fails, one is wont to take refuge behind the theory of "self-limitations," which led the first Dr. Warren many years ago, when asked what was good for acute rheumatism, to reply, "six weeks." Fortunately for us, text-books do not contain the whole of medicine and disease does not necessarily direct her course according to the tactics of a treatise on practice. We recognize nowadays, that if our joints are swollen and painful with acute articular rheumatism, we do not have to wait the whole six weeks, and we know that the old idea of "twenty-one days" as applied to typhoid fever does not hold, and that we have the peculiar types of disease known as *typhus levissimus*, *afebrile* and an abortive typhoid. The fact that we do have these peculiar types, whether it be the result of practice or in spite of practice, leads us to hope that disease of any sort which has once been aborted can be aborted a second time, and that after a while the *peculiar* type may become the *prevailing* type. It seems to me, that in the direction of abortive as well as of preventive medicine, our Section has a considerable scope for the future.

I wish to remind you that this is the centennial anniversary of Jenner's famous discovery, that persons accidentally inoculated with cowpox were subsequently insusceptible to smallpox. It is needless for me to do more than make mention of this fact and to recall the blessings which have accrued to the world from its introduction, how that one of the greatest blights to mankind, one that frequently decimated a population, has been blotted out and that the average limit of man's days has been increased in consequence.

It may not be aniss to mention the fact that these are the results of the purest clinical observation and not those of laboratory toil. I do not wish, gentlemen, to depreciate the results of experimentation and of exactness, so-called, but I do chafe under what at times, looks like absurd demand and unjust restriction. One is frequently reminded of Hamlet's fine frenzy: "Why, look you now, how unworthy a thing you make of me. You would play upon me; you would seem to know my stops; . . . 's blood! do you think that I am easier to be played on than a life?"

Gentlemen, I will not detain you further. An attractive program awaits us, and in its consideration I know that we shall derive pleasure and profit, and I trust that in succeeding years the Section on the Practice of Medicine may look back to its Denver meeting as productive of good and as a disseminator of knowledge; one accompanied as well with much pleasure.

ORIGINAL ARTICLES.

THE MODERN TREATMENT OF GUNSHOT WOUNDS IN MILITARY PRACTICE.

BY N. SENN, M.D.

LIEUTENANT-COLONEL U. S. VOLUNTEERS, CHIEF OPERATING SURGEON
WITH THE ARMY IN THE FIELD.

Two important causes are destined to bring about a radical change in the treatment of gunshot wounds as practiced in the war of the rebellion and as will be taught and advised in the Spanish-American and future wars: 1, the modifications which the weapon and projectile have undergone since that time; 2, the introduction into general practice of aseptic and antiseptic surgery. The diminution in the caliber of the bullet, the metallic jacket, the substitution of smokeless for black powder, the greater velocity and power of penetration of the missile, are conditions and influences which must necessarily modify the character of wounds inflicted with the modern weapon. Volumes have been written on this subject by writers in all countries in which the old weapon has been abandoned and the new one introduced. Numerous experiments have been made on cadavers and animals for the purpose of studying the effects of the modern projectile on the tissues with a view of obtaining reliable information as to the changes which will become necessary in the rational treatment of gunshot wounds in modern warfare. Experimental investigation has done much in pointing out some of the changes we may expect to see in the character of gunshot wounds during the present and coming wars, but many of the conclusions drawn from them will have to be modified after we have had an opportunity to study such wounds on a large scale on the battlefield. There can be no question but that the living body and the cadaver represent two entirely different mediums in studying the effects of the modern bullet. From a practical standpoint there remains no doubt as to the following facts, which will be confirmed by future experience in the treatment of gunshot injuries inflicted with the small caliber bullet: 1. Few bullets will be found lodged in the body. 2. Wounds will resemble more closely incised than contused wounds. 3. Range will have more influence in changing the character of the wound. 4. Diminished risk of infection. 5. Dangerous primary hemorrhage will be more, secondary hemorrhage less frequent. 6. More difficult extraction of the

bullet. As to the relative number of dead and wounded and the adaptation of the jacketed bullet to become encysted, are subjects on which we can only theorize and conjecture, subjects which can only be definitely settled by an extensive experience. We are better prepared to predict the influence wrought by the recent discoveries and advancements in surgery on the treatment of gunshot wounds and the fate of the wounded. The antiseptic treatment of wounds as taught and practiced by the immortal Lister, and asepsis as developed by the German surgeons with the distinguished Volkmann as their leader, are destined to minimize the remote dangers of gunshot wounds and other open injuries inflicted on the battlefield. We can safely repeat with the late Professor von Nussbaum, the most enthusiastic follower of Lister: "*The fate of the wounded rests in the hands of the one who applies the first dressing.*" This is the motto that every military surgeon must adopt and carry into effect. To this motto I should like to add a cast-iron rule that should never be transgressed and which, if observed without exception, will guard against one of the most fruitful sources of infection, and that rule should be: *Never probe a bullet wound on the battlefield.* The experience of the past has taught us the wisdom of adopting such a universal rule. As our enemy is armed with the Mauser rifle, the cases will be few where there is any indication for probing wounds, and in those few where the bullet has lodged in the body, exploration should be absolutely prohibited until the patient reaches the field hospital where the facilities for asepsis are at hand and instruments of precision in diagnosis can be employed in locating the missile.

FIRST AID DRESSING.

The idea of rendering first aid to the wounded immediately upon receipt of injury in modern warfare must be abandoned. Alarming hemorrhage from a large vessel of any of the extremities will in many instances be arrested by the patient himself or his nearest comrade by the use of some sort of circular constriction, but the legitimate function of the hospital corps men will begin after the engagement. Desirable as it may appear, attempts at disinfection of the wound or wounds will prove impracticable and useless on the battlefield. Time alone is an important element in contraindicating such a course. Hundreds and thousands may demand attention, to say nothing of the limited facilities for procuring for the wound and its vicinity an aseptic condition. The wisest and safest course to pursue under such circumstances is to make an intelligent use of the first aid dressing package which should be found upon the person of every soldier, officers and men. The average first aid package, the one devised by von Esmarch included, is too cumbersome. A first aid package, to meet the indications for which it is employed, should include: 1, an efficient antiseptic powder; 2, a sufficient quantity of a hygroscopic material to absorb the primary wound secretions and serve as a filter for the wound; 3, a handkerchief or bandage with which to retain the dressing and in case of necessity to be used in constructing a Spanish windlass; 4, safety pins. A few years ago I devised such a package. It contains about a teaspoonful of a powder composed of four parts of boracic acid, one part of salicylic acid, about one drachm of absorbent cotton, a piece of sterile gauze forty inches square and a number of safety

pins. The powder is lodged in the center of the cotton compress and is to be applied directly to the wound when the package is used. The package when compressed is small and wrapped in gutta percha. Every soldier of the Illinois volunteers carries such a package and is conversant with the manner in which it should be employed. The piece of gauze can be readily transformed into a Mayer triangular bandage and serves as an excellent substitute for Esmarch's bandage, which is heavier and requires much more space. The figures printed on Esmarch's bandage are useful for instruction but absolutely without value on the battlefield. In rendering first aid the injured part should be divested of clothing with as little disturbance of the wound as possible. Instead of removing the clothing it is much better to make free use of scissors and knife in gaining access to the wound. If two wounds are found, both must receive the same attention and care in protecting them against infection. I have used the antiseptic powder which I have referred to on a very large scale and can speak in positive terms of its potent antiseptic properties. It resembles in its effects on the tissues Thiersch's solution, being odorless, non-irritating and non-toxic. It forms with the cotton and primary wound secretions a crust which effectually seals the wound. In the absence of grave symptoms such as hemorrhage, this dressing should not be disturbed until the patient reaches the field hospital, and in many cases healing of the wound will take place without further interference. The immobilization of the injured part, particularly in cases of compound fracture of the extremities, constitutes an important part of the manifest duties of those who render first aid to the wounded. In all large engagements the supply of mechanical supports carried by the men of the hospital corps will be exhausted long before all of the wounded have received attention. Splints must be improvised. Rifles, sabers, bayonets, bark, branches of trees, shrubs, etc., the chest in fractures of the upper extremity, the opposite limb in fractures of the thigh or leg, will have to be utilized in procuring rest for the injured limb in transporting patients from the line of battle to the first dressing station. It is here that the surgeons will supplement or improve the work done by the litter bearers and hospital corps. It is for the purpose of doing away with the necessity of using splints that a German military surgeon has recently devised a litter on the plan of a double inclined plane for the lower extremities, a description of which he gave before the military section of the International Medical Congress held in Moscow last summer. In the absence of a litter of such special construction the same object is attained by securing the same position for the injured limb by a roll made of a blanket, clothing, knapsack, drum, straw, etc. It is my opinion that the transportation of the wounded suffering from a fracture of the lower extremity can be done with less pain and with greater security against additional injuries if the fractured limb is placed in a flexed than a straight position. If this statement is found to be correct by future observations the manner of dressing such cases must undergo a material change in the future. The manner of handling, carrying and conveying patients from the field to the hospital, suffering from fracture of the lower extremity, is a subject of great importance to those who have in charge the instruction of the hospital corps and company bearers.

ARREST OF HEMORRHAGE ON THE FIELD.

Life will be placed in jeopardy and deaths will occur more frequently from internal than external hemorrhage; in the treatment of the former little can be done in the field, and the latter class will come more frequently under the care of more professional men than surgeons. Ligation of arteries in the field will prove impracticable in most instances. The company bearers and hospital corps men should be fully instructed in the details of the various hemostatic resources applicable in emergency work. Elevation of the injured part, hyperflexion, digital compression and antiseptic tamponade are some of the measures employed which can be entrusted to intelligent and well instructed laymen in arresting hemorrhage. Some form of circular constriction will, however, most frequently be relied upon in arresting hemorrhage complicating gunshot wounds of the extremities. The advantages and dangers attending this method of arresting hemorrhage must be made a prominent feature in giving instructions on first aid. The technique of the procedure, whether it consists in the use of the typical Esmarch's elastic constrictor, a pair of suspenders or the Spanish windlass, must be fully explained and demonstrated on the living subject. The fact must be impressed that it is of great importance to render the limb that is to be constricted comparatively bloodless by elevation before the constrictor is applied. The next most important advice to be carried into effect in the use of circular constriction is to *constrict quickly and with sufficient firmness to interrupt at once and completely both the arterial and venous circulation*. A question of immense and far reaching importance, and one which has not as yet been definitely answered is: How long is it safe to continue the constriction? There must be, and there is, a limit as to length of time it is safe to exclude blood supply from living tissues. Although cases have been reported in which elastic constriction was continued for three to twelve hours without any serious immediate or remote consequences following, yet the consensus of opinion among surgeons, I am sure, at the present time would be opposed to excluding the blood supply from an entire limb, the seat of a gunshot injury, for a longer time than three to four hours. The danger of gangrene is always greater in constricting an injured than a healthy limb. A number of years ago I made an extended series of experiments on dogs to determine if possible, the maximum length of time it would be safe to continue elastic constriction. The limb was invariably constricted near its base. The time varied from an hour and a half to twenty-seven hours. In a number of cases temporary incompetence of the muscles and temporary paralysis followed when constriction was continued beyond four hours, but the degree of functional disturbance was not always proportionate to the length of time. In only one instance did gangrene occur, and in this case constriction was continued for seventeen hours, while the maximum time was twenty-seven hours. This subject is of special interest to the military surgeon, as from the very nature of things if circular constriction is resorted to as a hemostatic agent on the battlefield a considerable length of time must necessarily intervene before the wounded reach the first dressing station or field hospital, where it is removed and hemorrhage arrested by direct and permanent hemostatic measures. I should consider it dangerous to extend the time beyond from three to six hours, and should

insist that within this limit of time the patient should be placed in charge of a surgeon fully equipped to substitute for it the ligature, aseptic tamponade or some other direct hemostatic agent.

LOCATING, FINDING AND EXTRACTING BULLETS.

The new weapon will minimize the surgeon's work in locating, finding and removing bullets. In the vast majority of cases requiring surgical treatment two wounds will be found, the wound of entrance and exit marking the location and direction of the tubular wound made by the bullet. The cases in which the jacketed bullet will be found in the body indicated by the existence of only one wound will be exceptional. During my visit to the military hospitals in Greece last summer I found a good many wounds made by the small caliber projectile, but only in two cases could I obtain authentic information to the effect that the bullet was found in the tissues of the body and was removed by operative procedure. In the military hospitals in Turkey I found numerous cases in which the old-fashioned large caliber lead bullet used by the Greeks have been removed by operation or remained lodged in the body. The search for bullets in modern warfare, if made at all, will be reserved until the patient has reached the field hospital, when the surgeons will have at their disposal the necessary instrument for making an accurate diagnosis, and the essential facilities for making operations under the strictest aseptic and antiseptic precautions. Before using the finger or probe in exploration for a bullet the wound and the surface for a considerable distance around it should be thoroughly disinfected to guard against all possibility of infecting the wound during the examination or attempts at removal of the bullet, should such a course be deemed advisable after the completion of the examination. One of the most important rules to be followed in locating a bullet in the body is to place the patient and the part injured as nearly as possible in the same position as when occupied the moment the injury was received. The truth of this statement was well exemplified in the case of Gen. Hancock. A number of surgeons of good repute had made repeated attempts to find the bullet by probing but failed. At last he availed himself of the services of Dr. Reade, the present Surgeon-General of Pennsylvania, who placed the General in the same position he occupied in the saddle, and the first attempt to locate the bullet proved successful. The metal clad bullet has to a certain extent rendered the famous Nélaton probe obsolete. However, leaden bullets will be used to a greater or less extent by certain branches of the military force, and the porcelain tip will occasionally prove of service. The great objection to Nélaton's bullet probe is the size of the porcelain tip. *The end of the probe should correspond approximately in size to the caliber of the tubular wound.* By using an instrument constructed on this principle the danger of making false passages is greatly reduced. I have had a bullet probe constructed by Truax, Greene & Co., with two porcelain tips, one at each end rivited to the end of the silver probe, one 22 and the other 38 caliber. In parts of the body composed of deep muscular planes and layers of fascia it is often found absolutely impossible to follow the track of the bullet with any kind of probe. It is in such cases, when it is deemed prudent, from the symptoms presented and the probable location of the bullet, to explore the track that the surgeon will take

advantage of the use of the knife in dilating the track, using the probe step for step as a guide. The use of the X-ray will prove of the greatest value in all future attempts to locate bullets. In order to locate the bullet with sufficient accuracy to enable the surgeon to determine the propriety of an operation for its removal, and to guide him safely in his work photographs from at least two directions will have to be taken. Every field and general hospital should be supplied with an X-ray apparatus, and in all difficult cases this, one of the most recent diagnostic inventions, should be made use of before undertaking an operation, and in preference to repeated recourse to the probe. The famous old-fashioned American bullet forceps has lost its distinction in military surgery by the introduction of the metal clad bullet. The bullet forceps which I show you I devised a few years ago. It is so constructed that it serves at the same time as a useful bullet probe. The grip of the instrument upon any metallic bullet regardless of its caliber is firm, the bullet once grasped can be extracted without difficulty, as slipping of the instrument is almost an impossibility. It seems to me that when a small caliber bullet lodged in an important anatomic locality, difficult of approach and not giving rise to any serious symptoms, it should be allowed to remain with the hope that it may become encysted without causing any remote serious consequences. Such a conservative course in well selected cases will unquestionably yield better results than the too common routine practice to extract the bullet at all hazards.

GUNSHOT WOUNDS OF THE EXTREMITIES.

Besides the ordinary treatment of gunshot wounds regardless of the anatomic location of the injury, bullet wounds of the extremities, where complicated by fracture or joint injury, present to the surgeon special clinical features of great importance. Injuries of soft tissues not implicating important vessels and nerves, under modern treatment, should heal in a short time under the first dressing with little or no functional impairment. The existence of a gunshot fracture regardless of the extent of bone injury no longer furnishes a legitimate indication for a primary amputation. Such injuries under appropriate aseptic and mechanical treatment are amenable to a satisfactory repair in the course of time. They are the cases that tax the ingenuity of the surgeon in applying and maintaining the necessary mechanical support until the fracture heals by bony consolidation with the limb in a satisfactory useful position. In gunshot fractures of the femur extension and immobilization will now, as it has for a long time, constitute the generally accepted treatment. A determined, strong protest must be made against the unnecessary removal of detached and partially detached fragments of bone. If the wound remains aseptic the loose fragments of bone will not only retain their vitality but will take an important part in the restoration of the continuity of the bone and add materially to the functional result. Débridement, more or less extensive, only becomes necessary and should be performed in case the wound becomes infected. In such an event the loose infected fragments of bone should be promptly removed, free tubular drainage established, and the wound throughout subjected to thorough disinfection. If the ordinary measures should fail, continued irrigation with a saturated solution of acetate of aluminium will very often bring about the desired

results and obviate the necessity of an amputation. Fixation and suspension in such cases will not only procure comfort for the patient but will answer an excellent purpose in securing and maintaining coaptations and in facilitating drainage and irrigation. As soon as the fracture has united with sufficient firmness to render extension superfluous, the limb should be immobilized in a circular plaster of Paris splint, extending from base of toes to the groin, and in high fractures including the pelvis, after which the patient can be permitted to walk about with the aid of crutches. In gunshot fractures of the leg early immobilization in a circular plastic splint is to be advised and yields the most gratifying results. Watchful control of patients suffering from such injuries and treated by the use of the plaster of Paris bandage is essential in guarding against disastrous complications and in obtaining satisfactory functional results. Gunshot injuries of any of the large joints are now within the range of successful conservative treatment. I have seen in the military hospitals, both in Greece and Turkey, soon after the close of the war, gunshot wounds of the hip, knee, ankle, shoulder, elbow and wrist joints, not only recover without any operative interference whatever, but in many of the cases a fair degree of motion and good use of the limb rewarded the conservative treatment. The indications for primary amputation of a limb, or part of a limb, should at present be restricted to cases in which the nutrition is suspended or seriously threatened by the coexistence of vascular lesions incompatible with the vitality of the tissues at and below the seat of injury. In cases of doubt the soldier is entitled to the benefit of the same, and the conservative treatment should be carried to its ultimate limits until the appearance of complications demonstrate its futility and dictate the propriety of resorting to a mutilating operation. It is always more creditable to the surgeon to save a limb than to remove it, and the soldier is entitled to the benefit of conservative surgery as much as the civilian, and the plan of the military surgeon of the future should and will be to limit more and more the indications for amputations.

GUNSHOT WOUNDS OF THE SKULL.

It is my intention to limit my remarks under this heading to penetrating gunshot wounds of the skull. The few cases of this class of injuries that will come under the observation of the military surgeon will invariably require operative interference, provided it holds out any encouragement whatever of saving life. In case a bullet has passed through the skull and its contents the entire scalp should be thoroughly shaved and disinfected. The wound of entrance must be enlarged sufficiently to expose the perforation freely, which is then enlarged with chisel, DeVilbiss or rongeur forceps sufficiently to enable the surgeon to remove the loose spicula of bone, which are frequently found some distance in the brain. With a long eyed probe a strip of iodoform gauze large enough to loosely pack the tubular visceral wound should be inserted from the wound of entrance to the wound of exit, and the rough gauze drain made to project a few inches beyond the surface of each wound. Thorough capillary drainage of this kind will prevent accumulation of primary wound secretion in the interior of the skull, and will be of value in arresting capillary hemorrhage. A large hygroscopic dressing enveloping the entire scalp and covering both wounds, con-

stitutes the dressing and must be held in place by a few turns of plaster of Paris bandage. The drain must be allowed to remain until the danger of infection is passed, when it is to be removed gradually by shortening it every day or two. In case the bullet should be found lodged in the interior of the skull the wound of entrance must be treated in the same manner and the bullet located by the careful use of Flubrer's aluminium probe. A counter opening may become necessary in removing the bullet if it has reached the opposite side of the skull or when it has become deflected or arrested in its course near the surface of the brain, in case the locality in which it has become lodged warrants operative intervention. In all visceral injuries of the contents of the skull resulting from gunshot wounds capillary or tubular drainage or a combination of the two is indicated and should be continued until there is no further danger of infection, hemorrhage or accumulation of wound products, when the drain is to be gradually removed. The value of the X-ray in locating bullets in the interior of the cranium has as yet not been definitely ascertained.

GUNSHOT WOUNDS OF THE CHEST.

Penetrating gunshot wounds of the chest are attended by an enormous mortality owing to the physiologic importance of the organs which it contains. Visceral wounds of the heart and large blood vessels usually result in death in a few moments from acute anemia. Hemorrhage into the pleural cavity and into the large bronchial tubes interferes mechanically with the respiratory functions and frequently proves fatal in a short time and if the patient recovers from its immediate effects life is placed in danger by complications which so often are caused by the hemothorax. The accumulation of such a large quantity of blood in the pleural cavity is not incompatible with a speedy recovery, as when the blood is aseptic its removal by absorption is accomplished in a short time.

Experience during the War of the Rebellion proved that in gunshot wounds of the chest the chances for life were much better if the bullet passed through the chest than if it remained lodged in the body. I saw a number of soldiers of the Graeco-Turkish war that had been shot through the chest convalescent and in fair health a few weeks after the injury was inflicted. We have made little progress in the treatment of penetrating wounds of the chest. Direct operative treatment of visceral wounds of the heart and lungs is always attended by imminent risk to life from pulmonary collapse. This source of danger stands in the way of direct treatment of visceral wounds of the chest. Hemorrhage from wounds of the lung is often corrected spontaneously by the accumulation of blood in the cavity of the chest, causing temporary pulmonary collapse and tamponade of the tubular visceral wound by the formation of a blood clot. Free incision of the chest wall has been strongly advocated by several French surgeons in cases of penetrating gunshot wounds of the chest with a view of arresting hemorrhage by ligature, tamponade or the use of the cautery, but the profession on the whole, for good reasons, is opposed to such heroic treatment. Unless the source of hemorrhage is one of the intercostal or the internal mammary artery it is advisable to rely on nature's resources in arresting the bleeding. Hemorrhage from the intercostal arteries can be effectually checked by tamponade, using for this

purpose an hour glass shaped tampon of iodoform gauze. Rest in the recumbent position, with the chest slightly elevated, is essential in aiding spontaneous arrest of hemorrhage and in the prevention of complications. A rise in the temperature during the first forty-eight hours is no indication of the existence of sepsis, as with few exceptions it indicates a febrile disturbance, caused by the absorption of fibrin ferment, the so-called fermentation fever. Should later symptoms set in suggestive of septic infection, aspiration should be promptly resorted to and if not followed by speedy improvement no time should be lost in subjecting the patient to the same medical treatment as advised and practiced for empyema, that is, rib resection, free incision and drainage. The production of an artificial pneumothorax or hydrothorax by the introduction into the pleural cavity on the injured side of a non-toxic gas or filtered atmospheric air or sterilized water or non-toxic antiseptic solutions has not proved satisfactory in the treatment of intrathoracic traumatic hemorrhage. From what has been said it is clear that the best treatment in penetrating gunshot wounds of the chest consists in hermetically sealing the wound of entrance and exit, if such exists, under strict aseptic precautions and watch for and treat subsequent complications as they present themselves.

GUNSHOT WOUNDS OF THE ABDOMEN.

The greater part of this paper will be devoted to this subject, as recent discoveries and improvements in surgery have done more for the successful treatment of visceral wounds of the abdominal organs than the injuries of any of the organs contained in the remaining large cavities of the body. The triumphs that have signaled the practice of civilian surgeons in the operative treatment of intra-abdominal injuries must be repeated on the battlefield. I look hopefully for many successful results in the operative treatment of gunshot wounds in military practice. I will in this connection limit my remarks to penetrating wounds, taking it for granted that when patients suffering from abdominal wounds are brought to the field hospitals the surgeons in charge will consider it their imperative duty to make a positive distinction between penetrating and non-penetrating wounds before assuming the responsibility of opening the abdomen. In the discussion of penetrating wounds of the abdomen I shall quote freely from the forthcoming third edition of the American Textbook of Surgery from the chapter which treats of this subject. Sword, bayonet and other stab wounds will diminish in frequency with the development of modern scientific warfare. The penetrating wounds of the abdomen that will come under the observation of the military surgeon will with few exceptions be wounds inflicted with the modern small caliber projectile. The visceral wounds, the wound of entrance and exit will be small, too small for digital exploration. It is perhaps superfluous to make the statement here that *a penetrating wound of the abdomen should never be probed either for diagnostic or therapeutic purposes*. If any doubt exists as to whether or not the bullet has entered the abdominal cavity it is far better and safer to dilate the track by the use of the knife, relying on the probe as a guide, than to work in the dark with the probe and by doing so increasing the possibilities of infecting the peritoneal cavity. Quite recently the assertion has been made by several prominent surgeons that laparotomy should

be performed in all cases where it can be shown that penetration has occurred. It must, however, be admitted that, in the absence of serious visceral lesions, penetrating wounds of the abdomen are injuries from which the patients are very likely to recover without operative treatment, and that when such patients are subjected to laparotomy death may occur solely in consequence of the operation. It is undoubtedly true that in most cases of spontaneous recovery after penetrating gunshot wound of the abdomen the favorable termination has been due to the absence of serious visceral lesions, which some hold to be invariably present in such cases. A number of years ago I made a series of experiments on the cadaver for the purpose of demonstrating that occasionally a bullet can traverse the abdominal cavity in certain directions without producing a visceral wound that would warrant a laparotomy. The cadaver, a marasmic adult male was placed in the erect position against a wall and the shooting was done with a 38 caliber rifle at a distance of 30 feet. The bullet was fired in every instance in an antero-posterior direction and invariably passed through the body. Sixteen shots were fired and examination of the abdominal cavity carefully made by following the track of each bullet, showed that four of the bullets traversed the abdominal cavity without injuring the stomach or intestines or any of the large abdominal vessels. In each of these four experiments the bullet entered the abdomen at or a little above the umbilical level. In all experiments in which the bullet entered below the umbilical level intestinal perforations were found. Absence of visceral lesions has been also demonstrated during an operation or at the postmortem. During the Graeco-Turkish war several cases of gunshot wound of the abdomen recovered under a conservative plan of treatment. In nearly all of these cases the bullet entered the abdomen above the umbilicus, the most favorable location for the escape of intestines from the missile, the patient being in a standing position.

In two out of sixteen cases of penetrating gunshot wounds of the abdomen which came under the observation of the writer the absence of visceral injuries of the gastro-intestinal canal was demonstrated by the use of the hydrogen gas-test, and both of these patients recovered without resort to laparotomy. Clinical experience and the result of experiment show conclusively that laparotomy should not be performed simply because a bullet has entered the abdominal cavity, but that its performance should be limited to the treatment of intra-abdominal lesions which, without operative interference, would tend to destroy life. A bullet which passes through the lower part of the abdomen from side to side or obliquely is almost sure to produce from four to fourteen perforations of the intestines, while absence of dangerous visceral complications may be inferred with some degree of probability if it crosses the abdominal cavity in an antero-posterior direction at, or a little above, the umbilical level.

SYMPTOMS.

The general symptoms in cases of penetrating gunshot wounds of the abdomen, with the exception of those due to profuse hemorrhage, furnish very little information in reference to the existence or absence of visceral complications. Severe shock may attend a single non-penetrating wound; and it may be wanting, or at least slight, in cases of multiple perforation

of the intestines. It is not an uncommon occurrence for a patient who has received a penetrating wound of the abdomen to walk several blocks, or even a number of miles, without a great deal of suffering and without showing any symptoms of shock, and yet for a number of intestinal perforations to be revealed at a subsequent operation or autopsy. Vomiting occurs with equal frequency in parietal wounds and in simple penetrating wounds as when the viscera have been injured. Vomiting of blood points to the existence of a wound of the stomach.

Pallor is present in all penetrating wounds of the abdomen, soon after the receipt of the injury, and it is only more pronounced when produced, at least in part, by sudden and severe hemorrhage. Pain is very unreliable and often misleading symptom, as it may be moderate or almost completely absent soon after the injury has been inflicted, even when multiple perforations are present. The pulse at first is slow and compressible in all cases, and nothing characteristic in its qualities is observed even if the stomach or intestines have been wounded. Hemorrhage caused by wounds of any of the large organs, as the spleen, liver or kidneys, gives rise to progressive acute anemia, small rapid pulse, cold clammy perspiration, dilated pupils, yawning, vomiting, and in extreme cases, syncope and convulsions. The local symptoms are of no more value in determining the existence of visceral injuries in penetrating wounds of the abdomen than are the general symptoms which have just been enumerated. External hemorrhage is slight or entirely wanting, unless an artery or vein in the abdominal wall has been injured. The bleeding from visceral wounds gives rise to accumulations of blood in the peritoneal cavity, occult or internal hemorrhage; this can be recognized by physical signs which denote the presence of fluid in the free abdominal cavity and by general symptoms indicating progressive anemia; increasing pallor of the face and of the visible mucous membranes, small feeble pulse, superficial sighing, respiration and dilated pupils. Wounds of the stomach often occasion hemorrhage into this organ and hematemesis. Blood in the stools seldom follows hemorrhage into the bowels from intestinal wounds sufficiently early to be of any diagnostic value.

Circumscribed emphysema in the tissues around the track made by a bullet has been regarded as an important sign of the existence of intestinal perforation. This symptom is misleading and absolutely devoid of diagnostic value, as this condition has frequently been observed in non-penetrating wounds of the abdominal wall, resulting from the entrance of air into the loose connective tissue, or later by gas formation as one of the results of putrefactive infection. The accumulation of any considerable quantity of gas in the peritoneal cavity sometimes can be recognized by the disappearance of the normal liver dullness, caused by the presence of gas between the surface of the liver and the chest wall. This condition has been sought for in cases of perforating wounds of the abdomen as a diagnostic sign, and if found has been taken as a sure indication of the existence of visceral wounds of the gastro-intestinal canal. This is not, however, always the case. Adhesions between the surface of the liver and chest wall may have existed before the injury was received, or the amount of gas present may be insufficient to give rise to this sign. The escape of the contents of the wounded

stomach or intestines through the external wound, is a rare occurrence, and is possible only when the external wound is sufficiently large and straight and when it corresponds with the location of the visceral wound, or in the event of pre-existing adhesions between the abdominal wall and the injured portion of the gastro-intestinal canal. External extravasation occurs more frequently in wounds of the large than the small intestine. When this symptom is present it is conclusive proof of the existence of a visceral wound of the gastro-intestinal canal and the character of the extravasation will furnish reliable information as to the anatomic location of the visceral injury. With the exception of the last mentioned symptom and the indications pointing to the necessity of arresting internal hemorrhage, there is nothing about the local or general symptoms in cases of penetrating gunshot wounds of the abdomen that would enable the surgeon to decide with any degree of certainty soon after the injury was received, whether or not visceral injuries existed and consequently, whether laparotomy should or should not be performed.

DIAGNOSIS.

If a gunshot wound has penetrated the abdominal cavity and the general symptoms and local signs lead us to suspicion the existence of dangerous internal hemorrhage, *no time should be lost in further efforts to make an accurate anatomical diagnosis*, as sufficient evidence has been obtained to warrant a laparotomy for the purpose of preventing death from hemorrhage by the direct surgical treatment of the visceral injuries. If no such urgent indication presents itself it is desirable that the existence of visceral lesions demanding surgical treatment should be ascertained before the patient is subjected to the additional risk incident to a laparotomy, since a simple penetrating wound of the abdomen is an injury from which the majority of patients recover without operative treatment, and since visceral wounds of the gastro-intestinal canal are attended by such frightful mortality without surgical interference, the practical value and importance of a correct diagnosis before deciding upon a definite plan of treatment become obvious. It is apparent that if some reliable diagnostic test could be applied in cases of penetrating wounds of the abdomen which would indicate to the surgeon the presence or absence of visceral lesions of the gastro-intestinal canal, the indications for aggressive or conservative treatment would become clear. The writer has shown by his experiments on animals, and later by his clinical experience in the treatment of a number of cases of gunshot wounds of the abdomen that rectal insufflations of hydrogen gas can be relied upon in demonstrating the existence of perforations of the gastro-intestinal canal before opening the abdomen. He has shown conclusively that if the abdominal muscles are completely relaxed under the influence of a general anesthetic, hydrogen gas or filtered air can under safe pressure be forced from the anus to the mouth if no perforations exist, and if such are present the gas will escape into the peritoneal cavity, where its presence can be readily detected by the physical signs characteristic of a free tympanites or by its escape through the external opening. Theoretical objections have been made against this diagnostic test on the ground that it occasionally fails in demonstrating the existence of a perforation, and that it is instrumental in causing

fecal extravasation. In reply to this I must say that it has never failed in my hands in making by its aid a correct diagnosis, and the fallacy of the second objection I have shown repeatedly by experiments on animals. Hydrogen gas is a non-toxic substance, endowed with valuable inhibitory antiseptic properties, and is absorbed from all the larger serous cavities and connective tissue within a few hours. Pure zinc and sulphuric acid should be used in generating the gas, which is collected in a rubber balloon holding at least four gallons. The rubber balloon used for this purpose is square in shape and is connected with the rectal tip by means of a rubber tube six feet in length and supplied with a stop-cock near its proximal end. In applying the test an assistant presses the margin of the anus against the rectal tip, so as to prevent the escape of the gas, while another assistant forces the gas along the intestinal tube by pressing or sitting on the rubber balloon. The gas passes through the ileocecal valve under a pressure of two and a half pounds to the square inch and is announced by a distinct gurgling sound, which can always be distinctly heard by applying the ear or stethoscope over that region. If the rectum or colon has been perforated the gas will not reach the small intestine, as it will escape into the peritoneal cavity under less pressure than is required in rendering the ileocecal valve incompetent. As soon as the gas reaches a perforation large enough to permit its escape it will enter the peritoneal cavity and escape through the external wound if this has been freely laid open down to the peritoneum. If the external wound is in a location which points to injury of the stomach, this organ should be insufflated through a rubber stomach-tube, and if this test proves negative it is to be followed by rectal insufflation. It is impossible to inflate the intestines to any extent from the stomach.

TREATMENT.

The propriety of surgical interference in cases of penetrating gunshot wounds of the abdomen will depend upon one of three things:

1. General conditions of the patient.
2. Dangerous internal hemorrhage.
3. Wounds of the stomach or intestines large enough to permit extravasation. If the patient is pulseless and presents other indications of approaching death, operation is unjustifiable, as it would only hasten the end and bring reproach upon surgery and undermine the confidence in the life-saving value of the operation among the troops. Dangerous internal hemorrhage that will come to the notice of military surgeons in gunshot wounds of the abdomen will be the cases in which the vascular organs of the abdomen, the liver and spleen, or some of the larger vessels of the mesentery or omentum have been injured. Delay in such cases is dangerous. The abdomen should be opened and the hemorrhage arrested. The symptoms are apt to be unusually severe if the hemorrhage is sudden, progressive, if the loss of blood is gradual. In the latter case it may be prudent to watch the case for some time for more pressing indications, as it is well known that spontaneous arrest of hemorrhage may occur and large quantities of aseptic blood is removed from the peritoneal cavity in a short time. Visceral lesion of the gastro-intestinal canal large enough to permit extravasation are, with very few exceptions, mortal wounds, the existence of which can leave no doubt in the mind of the

surgeon to resort promptly to abdominal section as offering the only chance to save life.

PREPARATION OF PATIENT.

A patient suffering from a penetrating gunshot wound of the abdomen should be properly prepared before he is subjected to laparotomy. If the stomach is filled with food, a salt water emetic should be given for the purpose of emptying its contents, or better still, this can be done by the use of the stomach siphon tube. The rectum and colon must be emptied by a copious enema of warm water, to which may be added a tablespoonful of common salt. The unloading of the gastro-intestinal canal will not only facilitate the operation but will have a favorable influence in securing rest for the injured part. A hypodermic injection of gr. 1/4 of morphin and gr. 1/30 of strychnia should be given shortly before the anesthetic is administered, as these remedies in the doses specified assist the action of the anesthetic, secure rest for the intestines, and sustains the action of the heart. If the patient is much prostrated two ounces of whisky diluted with four ounces of warm water should be given by the rectum. The whole abdomen should be thoroughly disinfected. Before and during the operation the use of external dry heat will do much in preventing shock and in aiding the peripheral circulation. Compresses, towels and several gallons of warm normal solution of salt must be provided. The operator should do the work with as little assistance and as few instruments as possible, as the danger of infection in emergency work is apt to be proportionate with the number of assistants employed and number of instruments used. Hands, instruments, suturing material, in fact everything that is to be brought in contact with the wound, must be sterilized. In military surgery silk will have the preference over catgut. A hospital tent with a floor will be an admirable operating room in all semi-tropical climates. Anesthesia should be commenced with chloroform until the patient is under its full influence, when it should be continued with ether.

INCISION.

In the majority of cases the median incision should be made, as it affords advantages which give it the preference. It should always be selected in cases of gunshot wounds of the stomach, and where the wound of entrance is located near the median line. A median incision affords most ready access in the treatment of wounds of the small intestine. If the insufflation test is used, it will prove sometimes of value in deciding upon the location of the incision. If in gunshot wounds of the upper portion of the abdomen, direct inflation of the stomach through an elastic tube reveals the existence of perforation of this organ, the median incision should be selected. If rectal insufflation yields a positive result before the gas has passed the ileocecal valve, the incision should be made over the wounded portion of the colon, which is usually indicated by the course of the bullet. A wound in the transverse colon can be found and dealt with most effectually through a high median incision, perforation of the cecum or of the ascending colon calls for a lateral incision directly over the wounded organ, while a lateral incision on the left side is indicated if from the direction of the bullet it is evident or probable that the colon below the splenic flexure is the seat of the visceral injury. Laparotomy performed for the arrest of hemorrhage should always be done by mak-

ing a long median incision, which will afford the most direct access to the different sources of hemorrhage. Very often it will be advisable to make the incision in the line of the wound of entrance, more especially in cases where a lateral incision is indicated from the location of the wound from the course of the bullet, and perhaps from the results obtained by the insufflation test.

ARREST OF HEMORRHAGE.

In opening the abdomen in the treatment of internal hemorrhage the surgeon undertakes a task, the gravity of which it is impossible to foretell. To do the work quietly and well he must be perfectly familiar with the anatomy of the abdominal organs, their source of blood supply, and must have full knowledge of all hemostatic resources, the indication for their selection and details of application. Profuse intra-abdominal hemorrhage resulting from penetrating gunshot wounds of the abdomen is more frequently of parenchymatous and venous than arterial origin. Wounds of the liver, spleen, kidneys and mesentery give rise to profuse and often fatal hemorrhage. After opening the peritoneal cavity it is often very difficult to find the bleeding points, as the blood accumulates as rapidly as it is sponged out, and it becomes necessary to resort to special means in order to arrest profuse bleeding sufficiently to find the source of hemorrhage. One of two means should be employed: 1, intra-abdominal digital compression of the aorta; 2, packing the abdominal cavity with a number of large sponges or gauze compresses. Intra-abdominal compression of the aorta below the diaphragm can be readily made by an assistant introducing his hand through the abdominal incision, which in such a case must be larger than under ordinary circumstances. Compression made in this manner will promptly arrest the hemorrhage from any of the abdominal organs for a sufficient length of time to enable the surgeon to find the source of hemorrhage, and carry out the necessary treatment for its permanent arrest.

Hemorrhage from a perforated kidney may demand a nephrectomy, if it does not yield to tamponade. If the tampon is used an incision in the lumbar region must be made for the removal of the tampon and the parietal peritoneum should be sutured, so as to exclude the peritoneal cavity from the renal wounds. Wounds of the liver are sutured with catgut, cauterized with the actual cautery, or tamponaded with a long strip of iodoform or a typical Mikulicz tampon; in either case the gauze is to be brought out of the wound and utilized as a drain.

A wound of the spleen, if the hemorrhage does not yield to ligation, suturing or tamponade, necessitates splenectomy; very troublesome hemorrhage is often met with in wounds of the mesentery. When multiple wounds of the mesentery, and visceral wounds of the stomach or intestines are the cause of hemorrhage, it is a good plan to pack the abdominal cavity with a number of large sponges, napkins or compresses of gauze, to each of which a long strip of gauze is securely tied, these strips being allowed to hang out of the wound in order that none of the sponges or compresses may be lost or forgotten in the abdominal cavity after the completion of the operation. The sponges or compresses make sufficient pressure to arrest parenchymatous oozing as well as venous hemorrhage, if they are placed at different points against the mesentery and between the intestinal coils. The sponges

are removed one by one from below upward, and the bleeding points secured as fast as they are uncovered. The ligation of mesenteric and omental vessels, both arteries and veins, should be done by applying the ligature *en masse*. A round needle or Thornton's curved hemostatic forceps are the most useful instruments for this purpose. Catgut, as a rule, should not be relied upon in tying a mesenteric vessel, as it is greatly inferior to fine silk.

If hemorrhage is profuse this must be attended to before anything is done in the way of binding and suturing the visceral wounds. Troublesome hemorrhage from a large visceral wound of the stomach or intestines is best controlled by hemming the margin of the wound with catgut or fine silk. In hemorrhage from localities not accessible to ligation and not amenable to tamponade, pressure forceps are applied and allowed to remain for twenty-four or forty-eight hours. When used in this manner the instrument must be long enough to be brought out of the wound, and is then incorporated in the dressing. For the purpose of facilitating the binding and removal of the instrument a strip of gauze is tied to the handle.

SEARCH FOR PERFORATIONS.

A number of cases have been recorded, and I am sure many more have occurred, in which laparotomy was performed, one or more perforations sutured, and the postmortem showed that a perforation was overlooked, death resulting from extravasation and diffuse septic peritonitis. Such experiences are by no means limited to the practice of novitiates, but have occurred to men of large experience and in well equipped first class hospitals. The handling of the entire length of the gastro-intestinal canal in search for perforations requires time, adds to the shock of the injury and operation, and even if done by experts and with the utmost care, a perforation may escape the attention of the operator and become the sole cause of death. If the surgeon adopts this plan of detecting the perforations the work should be done systematically. The ileocecal region is the best landmark in beginning the search. From here the small intestine is traced in an upward direction, examining loop after loop and returning the intestine as soon as examined so as to avoid extensive eventration, which adds greatly to the danger of the operation. The large intestine is traced from the ileocecal region downward. In one of my cases a perforation of the rectum was found low down in the pelvis and certainly would have been overlooked if I had not used the inflation test, which promptly revealed not only its existence but also its exact location. If the air or gas test has been employed with a positive result before the abdomen was opened there will be no difficulty experienced in finding the first opening. If the stomach was inflated directly through an elastic tube, and the test has shown the presence of a perforation, a median incision is made from the tip of the ensiform cartilage to the umbilicus and the stomach is drawn forward into the wound. If no perforation is found in the anterior wall, the insufflation is repeated, and the escaping air or gas will direct the surgeon to the perforation. Through this perforation the stomach should again be inflated in search for a second and possibly a third perforation. In searching for intestinal wounds by the aid of inflation, further inflation should be suspended as soon as the lowest perforation has been found. If possible, the perforated portion of the

intestine should now be brought forward into the wound, and after emptying the intestine below the perforation as far as possible of its contents, including the gas or air, the bowel is compressed below the perforation by an assistant and the intestine higher up is inflated through the wound. As a matter of course, a perfectly aseptic glass tube should be inserted into the rubber tube in place of the rectal tip. The inflation is now carried as far as the second opening, when the first perforation is sutured, and after disinfection and emptying the intervening portion of its gas the intestine is replaced in the abdominal cavity. Further inflation is now made through the second opening, and if a third one is found the second is sutured, and so on until the entire intestinal canal has been thoroughly subjected to the test. By following this plan extensive eventration is rendered superfluous and the overlooking of a perforation is made impossible, likewise the objection to the test that reduction of the intestines owing to distension with gas or air is overcome if the intervening sections between the perforations are emptied of their contents before suturing the wound.

SUTURING THE PERFORATIONS.

The materials for suturing are an ordinary sewing needle and fine aseptic silk. Catgut should be dispensed with in all intestinal work. Trimming the margins of the visceral wounds is not only superfluous, but absolutely harmful, as it requires a useless expenditure of time and may become an additional source of hemorrhage. The same can be said of the Czerny-Lembert suture. All that is required in the treatment of a visceral wound of the stomach and intestines is to turn the margins of the wound inward and bring into apposition healthy serous surfaces by the continuous or by interrupted sero-muscular sutures, which should always be made to include fibers of Halsted's submucosa. From four to six stitches to an inch will suffice. If possible, wounds of the stomach should be sutured in the direction of the blood vessels, and transverse suturing of the intestine is necessary for the purpose of preventing constriction of the lumen. Defects an inch and a half in length, on the convex side, can be closed in this manner without fear of causing intestinal obstruction, while much smaller defects on the mesenteric side usually necessitate a resection, not only because the vascular supply in the corresponding portion of the intestine would be inadequate, but also because a sufficiently sharp flexion might be produced at the seat of suturing to become the immediate mechanical cause of intestinal obstruction.

ENTERECTOMY.

Enterectomy is often indicated in cases of double perforation and in marginal wounds of the mesenteric border. If in cases of multiple perforations it should become necessary to make a double enterectomy, and the intervening portion of the small intestine is not more than two or three feet in length, it is best to resect the same, as the immediate effect of the single operation will be less severe than that of a double resection with a corresponding double enterorrhaphy. After resection the continuity of the intestinal canal should always be restored by a circular enterorrhaphy, using for this purpose the Czerny-Lembert suture. Strips of sterile gauze are preferable to clamps in preventing extravasation during the operation. The gauze strip is passed through a small buttonhole made with hemostatic forceps in the mesentery near the

intestine and tied with sufficient firmness to prevent escape of intestinal contents.

IRRIGATION OF THE ABDOMINAL CAVITY.

This is necessary only if fecal extravasation or escape of stomach contents has taken place, an accident which, if it has not occurred before the abdomen was opened, should be carefully avoided during the manipulation of the wounded intestines. Flushing the peritoneal cavity with warm sterilized water or normal salt solution not only clears it of infectious material, but acts at the same time as a stimulant to the flagging circulation. The current must be sufficiently strong not only to fill the peritoneal cavity quickly, but to *flush it out*.

After completion of the irrigation, the patient is placed on his side and in this position the fluid contents of the abdominal cavity are poured out. The cavity is then rapidly dried with large sponges wrung out of a weak sublimate solution (1 to 10,000) or Thiersch's solution. Some surgeons have practically abandoned flushing of the abdominal cavity, and rely almost exclusively on sponging in removing pus and extravasated fecal material; others are partial to leaving the physiologic solutions of salt in the cavity, paying no attention to the peritoneal toilette practiced with conscientious care by all surgeons only a few years ago.

DRAINAGE.

To drain or not to drain, is the all absorbing topic among surgeons whose time and attention are largely engaged in abdominal work. I wish to place myself on record as being a strong advocate of drainage in all cases of abdominal surgery in which we have reason to believe that contamination of the peritoneal cavity has taken place by extravasation of contents of the gastro-intestinal canal or pus. In gunshot wounds of the abdomen complicated by visceral injury, the probability that infection has occurred must not be lost sight of, and the only safe course to pursue under such circumstances is to drain when you are in doubt. Cases which require irrigation should always be drained. Other indications for drainage are visceral wounds of the liver and pancreas and the existence of parenchymatous hemorrhage which can not be remedied by any of the different hemostatic measures. A glass drain reaching to the bottom of the pelvis, loosely packed with a strip of iodoform gauze, answers an excellent purpose. Occasionally multiple drains are indicated. The Mikulicz drain is to be depended upon in arresting troublesome surface oozing. Drainage must be suspended at once, or gradually, with the cessation of the primary wound secretion.

SUTURING OF EXTERNAL INCISION.

Incisions through the median line are rapidly closed by one row of silk or silkworm gut sutures, which are placed close together and include all the tissues of the margins of the wound. Incisions made in any other place are to be closed by buried catgut sutures uniting the peritoneum and muscular layer separately, and a superficial row of silkworm gut sutures including all the tissues except the peritoneum. A large hygroscopic compress composed of sterile gauze and absorbent cotton, held in place by broad strips of adhesive plaster, constitutes the proper dressing. The sutures are removed at the end of the second week, and the patient must not be allowed to leave the bed before the expiration of the fourth week. Four weeks in

bed and the wearing of a well fitting abdominal support for three to six months are the most reliable precautions against the occurrence of a post-operative ventral hernia. The drainage opening should be closed with secondary sutures, inserted at the time of operation as soon as the drain is closed, otherwise a ventral hernia will be almost sure to develop in the scar at former site of the drainage tube.

AFTER-TREATMENT.

Absolute rest must be strictly enforced. Opiates must be given in doses sufficient to quiet the peristaltic action of the intestines. Stimulants must be used to counteract the effect of shock and to restore the vigor of the enfeebled peripheral circulation. Absolute diet must be observed for at least forty-eight hours. During this time a mixture of brandy and ice water, in small doses frequently repeated, or iced champagne, is agreeable to the patient, as it quenches thirst, relieves nausea and exerts a favorable influence upon the circulation. If more active stimulation is called for to overcome shock and the effects of hemorrhage, whisky, strychnia, ether, musk, or camphor can be injected subcutaneously or by the rectum, while the peripheral circulation is restored by applying dry heat to the extremities and trunk. The subcutaneous infusion of one to two pints of normal salt solution is an excellent restorative and of special therapeutic efficiency in cases where the vital forces are depressed and life is in danger from the effects of hemorrhage.

Should symptoms of peritonitis set in, a brisk saline cathartic should be given at the end of forty-eight hours, as at this time the intestinal wounds will have become sufficiently united to resist the peristalsis provoked by the cathartic, while the removal of intestinal contents and the absorption of septic material from the peritoneal cavity thus attained are not only the most efficient means of averting a fatal disease, but also of placing the wounds in the most favorable condition for rapid repair. Reopening of the wound and secondary flushing have done little in arresting or limiting septic peritonitis. If the case progresses favorably, liquid food by the stomach can be allowed at the end of the second day, and light solid food at the end of the first week. Under ordinary circumstances no effort is made to move the bowels until the end of the third or fourth day. If early feeding becomes necessary in marasmic or exsanguine patients, this can be done by rectal alimentation.

From the contents of the paper the following conclusions can be formulated:

1. In theory and practice military surgery is equivalent in every respect to emergency practice in civil life.
2. The wounded soldier is entitled to the same degree of immunity against infection as persons in civil life suffering from similar injuries.
3. The fate of the wounded rests in the hands of the one who applies the first dressing.
4. The first dressing should be as simple as possible, including an antiseptic powder composed of boracic acid, four parts, salicylic acid, one part. a small compress of cotton, safety pins and a piece of gauze forty inches square.
5. Any attempt to disinfect a wound on the battlefield is impracticable.
6. The first dressing stations and the field hospitals are the legitimate places where the work of the hos-

pital corps and company bearers is to be revised and supplemented. All formal operations must be performed in the field hospitals where the wounded can receive the full benefits of aseptic and antiseptic precautions.

7. Probing for bullets on the battlefield must be absolutely prohibited.

8. Elastic constriction for the arrest of hemorrhage must not be continued for more than four to six hours for fear of causing gangrene.

9. The X-ray will prove a more valuable diagnostic resource than the probe in locating bullets lodged in the body.

10. Gunshot wounds of the extremities must be treated upon the most conservative plan, the indications for primary amputation being limited to cases in which injury of the soft parts, vessels and nerves suspend or seriously threaten the nutrition of the limb below the seat of injury.

11. Operative interference is indicated in all penetrating gunshot wounds of the skull.

12. Gunshot wounds of the chest should be treated by hermetically sealing the wounds under the strictest aseptic precautions.

13. Laparotomy in penetrating gunshot wounds of the abdomen is indicated in all cases where life is threatened by hemorrhage of visceral wounds and the general condition of the patient is such as to sustain the expectation that he will survive the immediate effects of the operation.

DISCUSSION ON PERFORATION PERITONITIS.

Presented to the Section on Practice of Medicine at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

By J. C. WILSON, Philadelphia; W. W. KEEN, Philadelphia; J. H. MUSSER, Philadelphia; C. G. STOCKTON, Buffalo; L. F. BISHOP, New York; H. A. HARE, Philadelphia; FRANK BILLINGS, Chicago; H. M. MCCONNELL, Pennsylvania; H. J. HERRICK, Cleveland, and J. W. COKENOWER, Des Moines.

J. C. WILSON of Philadelphia—The resources of modern surgery have greatly simplified the work of the medical clinician. Forms of visceral disease that long baffled the art of medicine now yield promptly to surgical treatment. In the general category of pathologic conditions thus transferred from medicine to surgery many are primary, many secondary to infectious or other processes. The greater number of them do not tend to spontaneous recovery, so that a pure expectancy is without avail, while that modified expectancy which consists in the administration of drugs for the relief of symptoms is futile as to cure. In point of fact symptomatic treatment, while it allays suffering, very often darkens council by deferring accurate diagnosis and too long postponing surgical intervention.

In the list of visceral diseases not yielding to medical treatment and sooner or later to be transferred to the care of the surgeon are the following: Empyema, which is to be treated by free drainage and in necessary cases by resection of the ribs; pericardial effusions, which if purulent, require free incision and drainage; large single abscesses of the liver; troublesome cases of cholelithiasis with persistent symptoms and empyema of the gall bladder, which Richardson of Boston has recently shown to be relatively com-

mon and amenable to surgical treatment; cysts of the pancreas; echinococcus cysts. As concerns the kidney, extirpation of the organ may be performed when it is the seat of malignant or other growths; nephrorraphy for the relief of symptoms due to displacement; hydronephrosis and nephrolithiasis may require operation; and as certain cases of stubborn nephralgia permanent relief results from incision of the capsule. In recent times the field of the surgery of the gastro-intestinal tract has been greatly extended. The establishment of gastric fistulæ in stenosis of the esophagus for purposes of alimentation; pylorotomy, the partial or total extirpation of the stomach; gastro-enterostomy and other devices by which mechanical obstructions have been relieved and life prolonged are practiced with success. The same is true with regard to operations for the relief of obstructive diseases of the intestines. Among the most brilliant and perhaps beneficent feats of surgery are the operations recently devised for the removal of the carcinomatous disease of the lower bowel. The surgical treatment of diseases of the appendix has led to a complete revision of the views held in regard to the diseases in this region and the establishment of principles which mark a new era in abdominal surgery. Scarcely less brilliant and radical, if not equally successful, is the recent surgical treatment of ulcerative lesions of the stomach and intestines, especially peptic ulcer and the perforating ulcer of enteric fever. Nor can I close this list without referring to the brilliant achievements of Macewen, Horsley, Keen and others in the management of intracranial tumor and abscess and to the operations for the destruction of the ganglion of Gasser for the relief of otherwise intractable neuritis of the trifacial, and to nerve-stretching and the excision of nerves in other forms of stubborn neuralgia, and to Quinke's spinal puncture, which, though thus far barren of results as regards treatment, has proved of the greatest value in diagnosis.

These fruitful encroachments of surgery into fields long almost barrenly occupied by internal medicine constitute great permanent advances in the art of healing. In fact one may challenge contradiction in saying that the greatest achievements of modern surgery are not so much in the improvement upon old methods as in the acquisition of new regions of usefulness. They bring the surgeon and the clinician into closer contact, into more useful co-operation. It is often said that the improvement in surgical technique has exerted a detrimental influence upon surgical diagnosis. If this be true a compensation has taken place, for the improvement in surgical technique has vastly increased the responsibilities of the medical clinician as regards prompt and accurate diagnosis. If the surgeon becomes more skilful and successful in new fields of operation, the physician must keep pace, nay, run ahead of him in promptness and skill in diagnosis, for it is under the latter's care that the greatest number of visceral diseases to be benefited by operation first come. In many conditions resulting from visceral disease the uncertainty of inadequate drugging now gives place to the precision of aseptic surgery; doubt and delay to the prompt employment of available resources. At any rate in operative interference in proper cases we avail ourselves of a definite procedure. It is of vital importance that practitioners should understand the limitations of drug therapy and recognize the point at which

surgery alone can be helpful. It is not necessary in this company to catalogue illustrations. The compressed lung after a time undergoes changes that forever prevent its expansion, and we have already reached a period in the history of medicine where extreme permanent deformity of the chest, the result of a neglected empyema, excites trains of thought far from agreeable to those interested in the higher medical education; or where the sudden perforation of a necrotic, over-distended gall bladder and the discharge of its infected contents into the peritoneal cavity can be viewed with professional complacency.

In the greater number of visceral conditions amenable to operative interference more or less satisfactory rules of management have been formulated. The progress of knowledge in this respect has in recent years been rapid. In many, nay, in most instances, dicta are provisional, not final, but the measures by which applied science makes progress, observation, comparison, experiment, tend steadily to throw out false views and unsatisfactory methods. Clear-headed diagnosticians and pathologists and experienced surgeons are in accord. Diagnosis being determined, but little difficulty arises as to the decision in regard to operable and inoperable cases. There are, it is true, unsatisfactory results. Complete failure and disaster frequently occur, but the successes are often real, permanent and brilliant. The profession has every reason to congratulate itself upon the achievements of visceral surgery.

In one field, however, the general conditions are different. Doubt and uncertainty hamper action. Tardiness in the recognition of imminent danger; indecision and hesitancy; a fatuous reliance upon drugs that can not cure and upon traditional applications that our forefathers would, with a tithe of our pathologic knowledge, have at once and forever discarded, too often lead up from the catastrophe of disease to the final catastrophe of death.

I refer to perforation peritonitis. Curiously enough, what I am about to say has practically no bearing upon purely surgical lesions followed by extravasation of the intestinal contents and infection of the peritoneum. The surgeons have settled that question upon a very definite basis and apparently for all time. Every hospital resident knows that a gunshot wound or stab of the abdomen demands immediate surgical intervention according to rule, and that his chief must be summoned without a moment's delay. Not to operate in such cases under ordinary circumstances would be to invite criticism of the gravest kind, even to raise the question of malpractice. Nor does the gynecologist in his more limited field occupy a position less secure. Symptoms indicating the rupture of the sac in extra-uterine pregnancy are no longer treated by opium or salines, but by the swift, precise, life-saving steel and suture. He is equally prompt and definite in his management of acute peritonitis occurring in consequence of pyosalpinx, a condition etiologically analogous to perforative peritonitis; and in suitable cases immediate operation is his only hopeful procedure in puerperal peritonitis.

In these conditions the proportion of successful results, that is, of lives saved, is the justification of his decision and promptness. For all these cases the surgeon and gynecologist have established for themselves satisfactory rules of diagnosis and clear principles for operation. The operable and inoperable cases are respectively recognized, with a strong lean-

ing toward courage. No *ignis fatuus* of drug therapy tempts from the firm ground of experience to the treacherous morass of a baseless hope. There is no question of expectancy or delay. Even the possibility of death upon the table, a disaster unduly fearful to the too conservative surgeon, receives no more than proper consideration. The worst cases, if they be not altogether hopeless, are subjected to immediate and well-devised treatment in accordance with rules already formulated and generally accepted, and the limitations of diagnosis are subordinated to the resources of an almost perfect technique. Thus in obscure cases exploratory incision is not only justifiable, it is imperative.

It remains for the medical cases, if they may be so designated, still to be enveloped in doubt and uncertainty; still to suffer the fatal risks of tardy diagnosis and a paltering indecision as to treatment. By medical cases in this connection I mean those coming primarily under the care of the medical practitioner as such, in contradistinction to the surgeon and gynecologist, or what amounts to the same thing, coming under that of the general practitioner when in his relation to his patient he is serving in the capacity of the worker in internal medicine.

Few of us adequately realize how large this group of cases is. Acute peritonitis, the result of infection by way of perforation of the wall of the alimentary canal or of other hollow viscus, rupture of abscess or by some other analogous process, is very common indeed. It is perhaps as much more common than ordinary traumatic peritonitis, as the visceral diseases capable of producing it are more common than homicide.

Aside from the traumatic and gynecologic cases the list of diseases in which acute general peritonitis may arise is most extensive:

1. In the alimentary canal, *a*, peptic ulcer, gastric and duodenal; *b*, enteric fever; *c*, appendicitis.
2. Other hollow viscera, the contents of which may be infected, *a*, the gall bladder; *b*, the pelvis of the kidney; *c*, the urinary bladder.
3. Rupture of abscesses, *a*, purulent pleurisy; *b*, subphrenic abscess; *c*, hepatic abscess; *d*, abscess of the pancreas; *e*, appendicular abscess, and *f*, other pus collections in regions in relation with the peritoneum.
4. Necrotic processes involving abdominal viscera, *a*, internal strangulation; *b*, intussusception; *c*, volvulus; *d*, embolism and thrombosis of the mesenteric vessels; *e*, gangrene of the pancreas or of the spleen; *f*, displaced kidney or spleen with twisted pedicle; *g*, acute hemorrhagic pancreatitis; *h*, fat necrosis.

In some of these conditions, as for example empyema, hepatic abscess, peptic ulcer with symptoms of appendicitis, the previous underlying disease can be readily determined and the patient has as a rule been under observation prior to the accident which causes peritonitis. In others, such as walking enteric fever or peptic ulcer without symptoms, the patient, while out of health, is able to be about and to attend in some manner to his ordinary duties up to the time of the accident. This is also true in some cases of conditions in which acute peritonitis supervenes upon or is associated with more or less extensive necrotic processes, as strangulation, volvulus and acute pancreatitis.

In cases in which the previous condition is known the sudden occurrence of the symptoms of peritonitis

bears a clear pathologic relationship to processes of the antecedent condition and a reasonably accurate diagnosis of the immediate cause of the inflammation of the peritoneum may be reached. Under such circumstances there are intelligible data for the guidance of the surgeon as to the site of the original lesion and the nature of the difficulties to be encountered. When, however, the symptoms of an acute general peritonitis arise in an individual not previously regarding himself as ill or who has not been under observation, the uncertainties of the case very often preclude diagnosis and the surgical procedure must be of the nature of an exploratory operation. But the distinction between the cases in which the immediate causal diagnosis can be made and those in which it can not be made is a matter of theory rather than of practice. It is the acute fulminant peritonitis that requires immediate consideration. Here is the question of diagnosis. If the diagnosis be correct the prognosis in the vast majority of instances without operation is fatal. Even under the most favorable conditions the percentage of recoveries will be comparatively low and this is just the point at issue. The medical cases must be placed upon the same basis as the surgical or traumatic and the gynecologic cases. In a large proportion of them the conditions for operation are more unfavorable, it is true, but a minority are now saved, and with the same promptness in operating and the same general recognition of the propriety of immediate operation this minority will be greatly increased.

"In the early stages when operative interference is advisable and not without hope, the symptoms may be grouped as follows:

- "1. Pain general, becoming local; or local, becoming general, according to cause.
 - "2. Tenderness, general, becoming local; or local, becoming general.
 - "3. Rigidity of the abdominal muscles.
 - "4. Vomiting, green. *Exceptionally absent.*
 - "5. Rise of pulse and temperature. *Exceptionally also absent.*
 - "6. Shock, varying in depth.
 - "7. Diminished peristalsis.
- [I have added the words in italic. J. C. W.]
- "In fully developed peritonitis, in which the wisdom of interference is questionable, the symptoms are:
- "1. Pain lessened or absent.
 - "2. Tenderness general.
 - "3. Distention excessive, replacing rigidity.
 - "4. Vomiting excessive, green or fecal.
 - "5. Obstipation; peristaltic movements not heard.
 - "6. Rapid and feeble pulse.
 - "7. High or low temperature.
 - "8. Lividity of abdominal skin: cold extremities.
 - "9. Peritoneal facies.
 - "10. Mind clear.

"In hopeless cases the above symptoms are increased with collapse; and the patient is moribund."

In hospital practice almost all the cases present at the time of admission the symptoms of fully developed peritonitis and most of them are already in a condition which precludes operation. They come in to die; many of them are admitted moribund.

The importance of the condition of the abdomen can not be over-estimated. The early rigidity is a

¹ Richardson and Cobb: Park's "Surgery by American Authors," vol. II, p. 386.

symptom of the utmost importance. My experience leads me to fear that its value is not sufficiently recognized by practitioners. To wait for distention in the diagnosis of general peritonitis is in the larger proportion of the cases to postpone operation until too late.

A well developed man, an athlete, 26 years old, complained of sudden pain in the epigastrium after exercising on the horizontal bar in the evening. The pain increased. I saw him the next morning, when the belly was flat, board-like in its rigidity, exquisitely tender and the seat of general pain. There was no rise in temperature. Operation was advised and additional counsel sought. Concurrence in my views as to the existence of acute peritonitis failed; operation was not endorsed; purgatives were administered. Ten hours later the patient died. Upon postmortem examination there was found a clean-cut circular perforating ulcer upon the anterior wall of the duodenum; general infective peritonitis; no other lesions.

A proportion of the cases are inoperable from the onset. Collapse occurs from which the patient does not rally.

A middle aged Italian in my service at the Pennsylvania Hospital in October, 1897, died within four hours of the first appearance of symptoms indicating perforation of the gut, at about the twentieth day of an attack of enteric fever. Perforation was found at the autopsy.

In a recent series of six cases of perforating ulcer of the stomach reported by different observers in which operation was performed within a few hours after the development of symptoms indicating perforation, five recovered.²

In Keen's recently published "Surgical Complications and Sequels of Typhoid Fever" there is a table of eighty-three well authenticated cases of operation for intestinal perforation in enteric fever. These cases were collected and carefully analyzed by Westcott. They give as a general result sixteen recoveries or 19.36 per cent. of cures and 80.64 per cent. of deaths. When this, as the author points out, is contrasted with Murchison's unchallenged figures of 90 to 95 deaths after perforation without operation we may well take courage for the future.

As regards the time of operation this table shows the following remarkable and most instructive facts:

"In the cases operated on within twelve hours, the percentage of recoveries was 26.7 per cent. Between twelve and twenty-four hours, 30 per cent. After twenty-four hours, the mortality was total, except one after twenty-six hours (No. 64) and the two that recovered between two and three days (Nos. 25 and 28)" And upon them Professor Keen makes this comment: "The last two cases we must consider as exceptional and not impairing the rule that if the operation is not done within about twenty-four hours after the perforation there is practically no hope of a recovery."

The following words of Keen with reference to operation in typhoid perforations are applicable to perforation peritonitis in general: "But, after all, the appeal must be to the facts in the case. This is the final arbiter. When once physicians are not only on the alert to observe the symptoms of perforation, but when the knowledge that perforation of the bowel can be remedied by surgical means has permeated the profession, so that the instant that perforation takes

place the surgeon will be called upon, and, if the case be suitable, will operate, we shall find unquestionably a much larger percentage of cures than have thus far been reported."

In conclusion I desire to formulate for discussion the following propositions:

As regards operation in acute general peritonitis due to perforation and analogous conditions,

1. A definite causal or local diagnosis of the lesions can be made in comparatively few instances.

2. The diagnosis of acute general fulminant peritonitis is of itself sufficient to justify operative interference in proper cases.

3. The earlier the operation the greater the prospect of success. After twenty-four hours, especially if great distention of the abdomen has shown itself, operation is not likely to be followed by recovery.

4. A small proportion of the cases are manifestly hopeless from the onset.

5. Where the patient is not obviously past hope the fear of death upon the table should not deter the surgeon from operating.

W. W. KEEN of Philadelphia—I have been in the Section on Surgery and Anatomy, but left there in order that I might be present in the Section on Internal Medicine, and I have been rewarded by so doing.

The catalogue of diseases which are shown as causing perforation peritonitis is sufficient to challenge our attention. But little time passes in which we are not called to see a case of perforation peritonitis from some cause. The urgency of these cases warrants a careful consideration of the whole subject of the treatment of perforation peritonitis; and also warrants the conclusions Dr. Wilson had reached and with which I am in full accord.

However, I do not agree with him as regards the symptoms which he has mentioned as being of value. The pulse and temperature in perforation peritonitis are of very unequal value. While, as a general rule, I believe the temperature to be the best index of a septic condition, yet it is actually of little weight or value. I remember a case of suppurative peritonitis in which the postmortem confirmed the diagnosis, where the temperature was at no time above 100 degrees F. In many cases the temperature is not above 99 degrees; in these cases the temperature is evidently of little value. However, if the temperature runs high or falls low, I respect it. I was glad to see that Dr. Wilson mentioned muscular rigidity of the abdominal wall as occurring in appendicitis, especially in perforation appendicitis.

Dr. Wilson, in quoting statistics, called especial attention to those operated upon within the first twenty-four hours; this is a matter of extreme importance. If we wait twenty-four hours after perforation we can assign the patient to the grave. Logic, reinforced by statistics, confirms the statement that, in typhoid fever perforation means a mortality of 95 per cent. Cases operated upon within twenty-four hours show that we can save nearly 30 per cent. Drs. Weir and Tincker collected seventy-eight cases, operated upon during sixteen years, which showed a mortality of 30 per cent.

In cases of appendicitis I am quite sure that this Section and the profession in general will agree that if perforation takes place, especially if it occurs without adhesions and localized abscess, operation offers practically the only hope, and the earlier it is done the better. As I do not think this Section objects to

² American Year-Book of Medicine and Surgery, 1898, p. 182.

surgical details I will say that Wells gives a table of ovariectomies in which the incisions were two and three inches in length, but I do not think that as far as the mortality is concerned it makes any difference if they are two or six inches long. In cases of appendicitis where perforation and general suppurative peritonitis has occurred, I know that the safety of the patient depends upon the thorough cleaning of the abdominal cavity.

I am quite sure the Section has taken up an important topic for discussion, one that touches the practical physician and surgeon, and we can unite and go arm in arm in the march for life and humanity.

Dr. J. H. MUSSER of Philadelphia—The subject has been so thoroughly and exhaustively considered by Dr. Wilson, supplemented by remarks by Dr. Keen, that I will not say much further except to speak of my personal experience in connection with this subject. I want to speak of perforation peritonitis arising from other diseases than typhoid fever. I am satisfied that it is very essential and important that we should early recognize the cause, and, if possible, the antecedent cause of perforation. Local rigidity, localized tenderness, with pain probably at first, followed by symptoms of shock, and especially the occurrence of vomiting, with increase of pulse rate, but not necessarily any change in temperature, all are important symptoms of this condition. If possible we should anticipate perforation. Pain continuing for twelve or twenty-four hours is of great significance and is one of great dread to me. There is no other symptom which I dread so much as this one of pain; when it does occur I am very apprehensive. If these cases be examined after death, we find a perforation that is preceded by a localized inflammation; a considerable amount of lymph covers the intestines in this region, and they are matted together, and in order to get at the point of perforation, one must separate these adhesions. The phenomena preceding this condition, consists of pain, the degree of which depends upon the intelligence of the patient at that time; a patient with typhoid fever is not susceptible to pain or else their state of mind is such that they do not complain of pain unless their attention is called to it. Pain, rigidity and localized tenderness is important, as Dr. Wilson has pointed out. Pain, localized tenderness, with an antecedent history of slight rigidity, followed by symptoms of shock, are the symptoms that should direct attention to perforation peritonitis. The occurrence of symptoms of shock, hemorrhage being excluded, are the ones that we must rely upon in making a diagnosis of perforation peritonitis. I am in accord with the opinion of the surgeon who makes an exploratory incision to make his diagnosis; it is certainly murder to wait. Cases occur from time to time in all our experiences, which are obscure, and which lead us into difficulty when it is not our fault that such cases are not distinctly recognized and promptly treated. I can no better illustrate what I mean than relate the history of a young girl, 14 years of age, who was seen in the first week of typhoid fever; the diagnosis seemed to be undoubted, although it is true the reaction did not verify the diagnosis. In the course of the disease, the temperature, the mental and intestinal symptoms all pointed to the fact that she had typhoid fever. At the end of the first week she complained of some pain in the abdomen; there

was no rigidity and she was without tympany. The day following, the pain was marked and severe in the back, and in order to exclude any pelvic disease—she had a discharge from the vagina—an examination was made and a large mass was found in the pelvis. I was somewhat mortified, for I thought I had been treating a case of pelvic abscess for typhoid fever. The surgeon that was with me agreed that such was the case. Evidences of general peritonitis being excluded we decided to operate. The patient died, and the autopsy showed that she did have typhoid fever, with perforation and peritonitis. There was also present a pelvic tumor.

Dr. STOCKTON of Buffalo, N. Y.—The question has been so ably presented by Dr. Wilson and so thoroughly discussed by members of the Section, that little is left to be said. Yet there are a few details that come up for discussion. In the first place it is a matter of great importance to discover whether the perforation has been one involving a hollow viscus, containing air like the stomach or intestines, or whether the gall or the urinary bladder. If we have a perforation from an abscess forming within the peritoneal cavity, the process is a more rapid one than that which occurs from an abscess forming in a solid organ and the symptoms are not so distinctive. The symptoms differ materially in different cases. Yet in my mind it is far from clear just when perforation is going to occur in a slow developing case. There is not much difficulty in the diagnosis and early recognition of perforation from a peptic ulcer, yet the symptoms sometimes mislead a very careful man. One case I will relate illustrates what I mean. A colored man was picked up who was in collapse and in intense pain. This pain was in the region of the bladder. The man was sent to the hospital, and we supposed that he was suffering from rupture of the bladder. For some reason an operation was not performed. The man survived nearly a week and then died. The autopsy showed perforation of the stomach. There was a round ulcer, which had opened into the abdominal cavity discharging the gastric contents there; yet after this the man survived several days. He had urinary pain and tenderness over the bladder, but no vomiting. To my mind the point that should stand out as the best guide to perforation of the stomach, intestines, gall-bladder or the urinary bladder is the suddenness of the onset of the symptoms. It is true, as Dr. Musser has said, that perforation may be preceded by slow inflammatory process preceding tympanites before symptoms of shock occur. There are symptoms which can not be referred to any particular part of the abdominal cavity. The sudden onset of pain with rigidity of muscles and a condition approaching shock makes out a case of perforating ulcer of the stomach. On the other hand, a man has often to deal with cases in which there is tenderness and rigidity of the muscles and pain, and the case goes on for several days with increasing symptoms and tympanites, and it is not easy to tell when perforation occurs. It is interesting to note the frequency with which pain is discovered remote from the time at which perforation occurs. My views of the symptoms must not be considered different from those already expressed. I should like, however, to state that it often happens that there is an absence of the symptoms one most expects, and one is so often surprised at the postmortem to find that such is the case. I have been so surprised time and again. These cases

do occur, and it is for this reason that attention should be called to details and symptomatology of peritonitis. Surgery of this field should be studied more closely. A fact that is indisputable is that perforation peritonitis is followed by certain death without operative interference. The difficulty arises, I think, when we have to determine whether we have perforation in certain class of cases.

Dr. BISHOP, Pennsylvania—A point of great importance was not emphasized. I refer to the use of opium. Opium obscures diagnosis and gives false confidence to the laws of life. I would like to call attention to the fact that relief of pain can be obtained by the use of ice-bags. This winter a physician consulted me who was suffering from peritonitis. That man never stopped speaking of the comfort he got from the use of rubber bags filled with cracked ice, which was laid upon the abdomen constantly for a number of days. It is of great importance to know that pain can be relieved by ice and so we can avoid the use of opium.

Dr. HARE of Philadelphia—The character of the pain has not been sufficiently emphasized. I confess that I have not had the experience in cases of perforation in typhoid fever that Dr. Keen has had. The surgeons get the idea that these cases occur quite frequently in the hands of the medical practitioner—much more often than they do occur. Statistics show that they do not occur with as great a frequency as one would imagine from Dr. Keen's remarks. In the few cases that I have seen are two classes. One case I recall was that of a student who was lying quietly in bed who was suddenly seized with pain; he screamed in agony and died two or three hours after the onset of the pain. Another case I recall was one in which the pain commenced gradually and at the end of twelve hours began to be insupportable. To pursue these cases one should have a postmortem. In the first case there was present a perforating ulcer of the bowel. In the other case, owing to an ulcerative process going on, and an inflammatory action there, the intestines were glued together, etc., and the general symptoms of peritonitis developed. It is a mistake to believe that a perforation in typhoid fever must be accompanied by violent pain, or slowly oncoming pain. Last summer I saw a case that had an attack of abdominal pain as violent as that of peritonitis; it was apparently one of wind colic and the passing of fecal matter relieved the pain.

In these cases I do not believe there is a more anxious surgeon than I. I believe in having a surgeon to operate who uses his judgment and wisdom.

Dr. F. BILLINGS of Chicago—I thank Dr. Wilson for the clear and general outline he has given us. The enumeration of the symptoms he has given us no one can deny as being accurate. Of course there are exceptions to the general symptoms as laid down by Dr. Wilson, and no one individual is present who could not recite some case where one or all the symptoms were present.

I want to emphasize some of the things already said, and especially the points mentioned in regard to the antecedent history of these cases, which I consider so important—quite as important, or more so, than the symptoms already enumerated. One must remember that it is the exceptional cases which are of the greatest importance to us, and not so much those that are classic in form. Pain is enumerated as an important symptom, yet pain may exist up to the time of perforation and then suddenly cease; all of

us have seen this happen. I have seen cases of perforation in appendicitis in which the patient seemed to be in a perfectly normal condition so far as pulse and temperature was concerned; there were no physical signs to show that there was anything the matter; the pulse was normal, the abdomen was flaccid, with no points of tenderness. But pain suddenly coming on, operation was advised and done and there was found a rupture of the appendix.

There is another thing about which I wish to speak, and that is in regard to rigidity of muscles, which is always present and always may be found.

It is the exceptional points which appeal to an individual. But the lines as laid down by Dr. Wilson are no doubt true in general terms.

H. M. McCONNELL of Pennsylvania—There are two important points of diagnostic interest that I should like to mention, absence of elevation of temperature and rapidity of pulse rate. In cases that I have seen in consultation I have had the greatest trouble to impress upon the attending physician that the absence of temperature indicates that there is no peritonitis present. I could not imagine a case of peritonitis where the pulse remained at the normal point for any length of time. I can not conceive any case of perforation where the pulse is normal.

Dr. H. J. HERRICK of Cleveland—I recognize that the discussion is upon suppurative peritonitis; the conclusions are well taken and the symptoms well given, but this question has not been entered upon, it seems to me.

Dr. COKENOWER of Des Moines, Iowa—I wish to emphasize a point in regard to the use of opium; this drug relieves the pain and it is then almost impossible to get the consent of the patient for operation.

Dr. WILSON of Philadelphia—I wish to emphasize one or two points which, it seems to me, has been overlooked. The purpose of my paper was to use such influence as I had with the profession to urge upon them the necessity of referring cases of acute peritonitis, arising suddenly, to the surgeon; and the surgeon should treat these cases. The medical cases should be recognized and managed the same as surgical cases are recognized and managed. These are not cases for the medical practitioner. In a large hospital in a large city I asked the medical director certain questions; he said that among 3000 in-door cases there were a great many cases of acute peritonitis that were brought into the hospital who died within twelve hours. Many of them upon admission were drugged with opium, either to relieve their pain or uncontrollable vomiting. I am pleading for the lives of people, under these circumstances. The medical practitioner, outside the hospital, who see these cases first should recognize them and not drug them with opium, or else they should call to their aid an experienced and skilled surgeon. They then will be looked upon, recognized and managed as surgical cases.

In regard to what has been said in the discussion, I wish to state that we all know that perforation peritonitis comes on in various ways; it may come on like shock. There are cases in which, owing to the mechanical condition present, there is a little rent, through which follows a local infection. This gives rise to an adhesive peritonitis which is local. Other symptoms are produced later.

I am pleading for the lives of those that die in the

first three, four or five days, many of which might be saved.

I must say a word on another point. Every now and then there occurs a case in which the symptoms are not classical and not well defined. The case shows no pain—none at all in the right iliac region. Presently comes on tympany and the patient appears to be ill and the case looks like peritonitis. Cases of this kind of acute peritonitis are not general. I have met with several cases like this. Eight or nine years ago, a girl had an attack; Dr. Keen and I watched the case thirty-six hours; she got well without operation. I have seen other cases, two years ago, and again quite recently—within six weeks—a woman presenting the same symptoms. The point is this: These cases are not different from cases of fulminating explosive peritonitis in the hands of the medical man and they are not to be drugged with opium.

SOME PATHOLOGIC AND CLINICAL PHASES OF GALL-STONES.

BY A. H. CORDIER, M.D.

PROFESSOR OF ABDOMINAL SURGERY IN KANSAS CITY MEDICAL COLLEGE.
KANSAS CITY, MO.

Among the most common diseases of the abdominal cavity may be mentioned those of the biliary ducts, and of this class cholelithiasis is the most frequent. In fact, so common is this condition that in several thousand postmortems no less than 7 per cent. of cases with gall-stones were found, and it is a curious conclusion to which some clinicians have arrived, that as these cases did not present any evidence of the presence of the stones, it proves that the majority of those suffering with gall-stones will get well if left alone. Many cases of gall-stones present no direct testimony of their presence, while others give evidence in the most emphatic symptomatic language.

The causation of the formation of gall-stones has been a theme for discussion for many years by some of the ablest clinicians. A few years ago in the direct causes were enumerated stagnation of bile, inspissation of bile, advanced age, sedentary habits, tight lacing and abdominal tumors, all in a measure acting in the same way; that is, interfering with the free circulation of the bile.

The bile is a watery secretion containing 1 to 3 per cent. of solids, with bile pigment and bile acids as normal ingredients. It would seem in the young (under 20) the disease is rare, and that the age of 40 furnishes the largest number of cases until the age of 60 is passed, then the disease becomes relatively more frequent, and after this age there are fewer cases presenting symptoms pointing to the presence of stones (colic, etc.) Old people are more frequently affected with malignant diseases in the pyloric and duodenal segments of the alimentary canal, and modern pathologists recognize in the presence of gall-stones a factor in the production of these neoplasms; hence they are treated for the results and not the original cause.

Most of my cases have been in males. Most writers place the proportion at females five to males one. The cause especially present in females being tight lacing, laxity of abdominal walls, child-bearing—90 out of 115 cases in females had borne children.

Lunatics, from their sedentary habits, are said to be prone to gall-stones. I do not believe that idleness alone ever produced them; if so, the disease

would be more prevalent; heredity is not a cause, nor diet alone unless of a character to induce a gastro-duodenitis. The normal ingredients of the bile entering into the formation of gall-stones are bilirubin, biliary salts and cholesterin in abnormal quantities, often found in the gall-bladder. A pure cholesterin stone is rare and usually has some other ingredient as the nucleus. Those found in the hepatic ducts are, as a rule, the bilirubin-calcium stones, while those in the gall-bladder have bilirubin-calcium as a nucleus with cholesterin on this nucleus; the original focus having its origin in the hepatic duct and subsequently finding its way into the gall-bladder. The little hard, round, solitary stones found in the ductus choledochus are, as a rule, of bilirubin-calcium. Most stones are found in the gall-bladder, for it is here that the conditions most favorable for their formation and retention exist.

The old writers maintained that these stones were the result either of an overproduction of cholesterin by the liver or to a want of its proper solvent in the bile, thus permitting the substance to deposit and form stones. Later authors say that cholesterin is a result of disintegration of the epithelium of the mucous membrane and glands of the gall-bladder and larger bile ducts. Cholesterin is a substance of wide distribution over the body. It is found in various solids and fluids, in the expectoration of consumptives, in pus especially, in locations where there exists a mucous membrane. In bile from the liver .07 parts per 1000 of cholesterin is found, while the analysis from bile in the gall-bladder shows 3 to 11 parts per 1000. Occasionally pure masses of cholesterin are found in the gall-bladder. The preponderance of the evidence is against the old theory that these stones are formed by the bile failing to hold in solution the cholesterin, which was formerly held to be an abundant normal constituent of the bile. It would appear that cholesterin is formed in the gall-bladder and is in the bile as an emulsion. Bilirubin calcium is an insoluble compound, the outgrowth of the union of bilirubin and the lime salts. The bile salts sodium-glycocholate and taurocholate prevents this union naturally, even in the presence of a moderate excess of lime, but if an abundance of lime is added a precipitate of bilirubin-calcium results.

If to a weak ammoniacal solution of bilirubin there is added a few drops of lime water, an immediate precipitate of bilirubin-calcium takes place. If now to this same solution 2½ per cent. of glycocholate of soda be added it takes five times the quantity of lime water to cause any precipitate at all. This experiment has an important bearing in a prophylactic way.

Albumin favors the precipitation of bilirubin-calcium. The outpouring of a catarrhal change in a mucous membrane is largely albuminous. A gastro-duodenitis may lead to the stagnation of bile and thus act as one of the prime factors in the precipitation of this fluid, but it is not alone sufficient, for as long as no septic micro-organisms are present the disposition of the bile is to hold the stone-producing ingredients suspended or in solution. The bacillus coli communis is often the cause of catarrhal changes in the biliary passages. Nannyn found that if he injected the bacillus into the gall-bladder it excited no inflammation, but if the common duct was previously ligated the most intense cholecystitis was excited.

An infection of the gall-bladder gives rise to an

increase in the amount of cholesterin by destruction of and disintegration of the epithelial cells, and to a precipitation of bilirubin-calcium. The latter acts as a nucleus for most stones. The attacks of cholangitis may be of a transient character and yet leave the nuclei of many stones in the gall-bladder. These may or may not give rise to any symptoms directly attributable to their presence, yet the presence of stones in the gall-bladder may produce an influence on the general health of the individual that may become of a serious character.

Early diagnosis in many cases means prophylaxis. Obstructive jaundice, hepatic colic and ptomain poisoning are usually late manifestations. If in 10 per cent. of all postmortems there are found gall stones that were not suspected during life, owing to absence of symptoms of a severe nature, I am sure a close inquiry in some of these cases would have elicited a history of "bilious attacks," recurring headaches, a sense of uneasiness in the gall-bladder region, loss of weight, etc. If no infection exists when stones are in the gall-bladder their presence does not excite much pain, but when a stone becomes lodged in the common or even in the cystic duct then a paroxysm known as hepatic colic will supervene. Probably only two-thirds of patients with gall-stones ever have severe colic symptoms, but it is not the pain that kills in these instances.

Spasmodic closures of the pylorus may be mistaken for hepatic colic, but with a recognition of the accompanying gastric dilatation and by hyperacidity in these cases, a diagnosis can usually be made. It is not necessary that suppuration exist in order to have rigors and fever, the so-called "hepatic intermittents" of Osler. These irregular chills are due to the absorption of ptomains. When the stones are located in the common duct near its entrance into the duodenum absorption is especially liable to take place, for it is at this point that the lymphatics abound most plentifully. A small round stone will frequently become lodged just at this point and make for itself a bed in the mucous membrane by destroying the epithelium, thereby opening the avenues of lymphatic absorption. A stone in this location may remain for an indefinite period, giving rise to symptoms of a mild or severe character, depending on its disposition to become wedged into the duct and the completeness of this closure. These ball-valve stones are the most persistent in duration, the greatest in danger and the most difficult to cope with surgically. A stone lodged at this point and remaining for months or years is dangerous from the persistence of its health undermining properties, in a mild and gradual way (chronic sepsis and persistent mild cholemia) and from the remote danger of a cancerous development at the site of constant irritation. Where the obstruction is complete the ducts and gall-bladder become greatly distended with the bile and other normal and abnormal fluids. The lymphatics take up the coloring matter, distribute it through the blood channels to the whole mucous and cutaneous surfaces and thus jaundice is produced. A remarkable change takes place in the gall-bladder in some of these cases in which the common duct is occluded; that is, the bladder becomes contracted instead of dilated; this is in part explained by the action of Heister's valve and in part to the often present pericholangitis. A persistent and complete closure of the ductus communis choledochus frequently leads to cirrhosis of the liver.

The choledochus stones are found in about 10 to 15 per cent. of all cases presenting marked symptoms. Thornton (1848) was the first to remove a stone from the common duct, since which time the operation has been performed by many surgeons all over the world. Within the last five years the histories of cases have been carefully studied for the purpose of making early and correct diagnoses; this has led to an analysis of the symptoms, making it possible to differentiate stones in the gall-bladder from those in the common duct. The specific gravity of gall-stones is very light, 1020 to 1030, while that of bile is 1030. A ball-valve stone may float about in a dilated duct, changing its position easily. This in part explains the sudden cessation of the pain in some cases of colic, even though the stone does not escape into the duodenum. A change in the position of the body may cause a dislodgement of a light stone, provided the stone is not partially imbedded in the surrounding structures.

The function of the gall-bladder is not that of a reservoir for the bile, as it holds but an ounce and a half, while the twenty-four hours' secretion is about forty ounces. I believe the gall-bladder has some especial function. Most likely a digestive ferment is manufactured here in the quiescent stage of the liver.

The gall-bladder has been removed (Von Laugenbuck, 1802) successfully several times, but so far no scientific clinical data is available bearing on the progress of these cases, post operative. Upon a proper diagnosis depends the correct management of these cases. Were the obscure symptoms presented by many chronic invalids interpreted correctly a goodly number of the cases would prove to be cholelithiasis. Many a swarthy (icteric tinge) patient with loss of weight and interference with digestion and proper assimilation will, I believe, be found to have gall-stones stored away in the bile passages, and that their presence has interfered with the formation of some especial digestive agent, or has given rise to the development of noxious substances which have gradually undermined the health.

While jaundice is an indication for surgical interference, it is at the same time quite a serious bar to operation, as these chronic cholemic patients are, almost without exception, bleeders and they stand surgery and anesthetics very badly. All arguments favor early surgery where symptoms point to its necessity at all.

The treatment of these cases depends upon the symptoms. An ordinary attack of hepatic colic, due to the passage of a small stone will, in all probability, terminate favorably within a few hours or days, and if the stone was the only one present and succeeded in finding its way into the duodenum the case will require no farther care. If the case is one with well marked ball-valve symptoms, the stone will probably remain in the duct, giving rise to painful and dangerous symptoms until its surgical removal is effected. If the stones are in the gall-bladder and are giving rise to infection or suppuration in this viscus then an operation should be early resorted to. It is rare that pain alone, as a persistent symptom, forms an operative indication, yet frequent exacerbations of pain with the usual attendant symptoms of jaundice may demand operation. The mortality in skilled hands is very low. The surgery is difficult and requires careful anatomic discrimination, a familiarity with the pathology and exact surgical acumen. If these

essential prerequisites are not possessed by the operator, his work will show imperfect results and high mortality.

DEDUCTIONS.

1. Cholelithiasis is of frequent occurrence and usually gives rise to symptoms either severe or obscure.
2. Cholesterin as a gall-stone producing agent must be present in an abnormal quantity.
3. Cholesterin is in a great measure a product resulting from the destruction and disintegration of the epithelium of the biliary ducts and gall-bladder.
4. Bilirubin-calcium, an insoluble compound formed by the union of bilirubin and the lime salts, forms the nucleus of most of the stones formed in the gall-bladder.
5. Jaundice, ptomain poisoning and suppuration are late symptoms of cholelithiasis.
6. Dyspeptic symptoms, swarthy skin, uneasiness in the region of the gall-bladder (congestion of liver) and loss of weight are some of the remote and local symptoms of the presence of gall-stones.
7. Inflammatory diseases of the duodenum and bile passages are the most direct causative factors in the production of gall-stones.
8. The surgery of these cases is especially difficult and the inexperienced should not undertake it.
9. A ball-valve stone usually continues to give rise to symptoms until removed by surgical means.
10. Stones in the gall-bladder, producing septic symptoms, should be removed.

A NOTE ON THE TREATMENT OF CARCINOMA OF THE UTERUS.

BY J. H. ETHERIDGE, A.M., M.D.

PROFESSOR OF OBSTETRICS AND GYNECOLOGY, RUSH MEDICAL COLLEGE, IN AFFILIATION WITH THE UNIVERSITY OF CHICAGO.

The improvement in the condition of several cases of uterine cancer under the treatment herein described seems to me worthy of record. The idea of curing cancer by means of remedial agents has never found lodgment in my mind. Many patients have inoperable cancers; many others can not pay for the surgical operations in vogue for cancer today, and remain at home and suffer horribly till death comes to them as a welcome visitor. To such people, the treatment by the carbid of calcium will be a blessing. In two cases, the first ones treated by this agent, there was such a complete abolition of the trilogy of symptoms so characteristic of uterine cancer, viz.: discharge, odor and hemorrhage, one could easily be tempted to call them cures, did I not feel that I ought to wait at least two years for a possible return of the disease locally or remotely.

This dreadful disease has until very recently had but one termination, viz., the death of the patient. I know of no more loathsome malady in its last stages. The odor of it fills the sick room *ad nauseam*. I have known it to fill the entire house for weeks and months before death finally came. It so saturates a doctor's clothes that he can smell and fairly taste it the balance of the day. I know of no disease that emits a more repellant and disgusting offense to human nostrils.

In considering this subject, it is thought best to pass in review the investigations and opinions of the present day on the pathology of cancer. After that will follow the consideration of the carbid of calcium

and acetylene gas, the remedial agent used. Lastly, the cases treated will be presented.

An experience of seventeen months is too brief from which to draw lasting conclusions. Reports by many different observers from different countries are necessary to furnish results which shall remand the use of carbid of calcium to its proper place. It is desired to offer this initial paper as a contribution to the treatment of one of the most fatal diseases of the human race. Originality in discovering the application of this agent in its use herein described is distinctly disclaimed.

Recently vaginal hysterectomy has afforded one means of dealing curatively with this fell disease provided the operation be performed early enough. We never know in any case whether the operation be performed early enough to forestall death. I have done vaginal hysterectomy for uterine cancer when it occupied a space not larger than my thumb nail and have seen the patient die in less than thirteen months from a recurrence of the disease. Again, I have removed a uterus whose cervix had been wholly eaten away by carcinoma and seen the patient alive and well five years after the operation. I therefore conclude that vaginal hysterectomy can not be depended upon to bring lasting results in all cases. Indeed, I have seen so many cases of recurrence after total extirpation that I have long been searching for some means that promises better results. I have used many much praised remedies, and have turned away from them because of their failure to secure curative results. I used Chian turpentine faithfully, which I had had imported from London so as to be certain that I was using the article so much vaunted by Clay of Manchester, several years ago. It was a complete disappointment. Alcohol, greatly praised recently, used in parenchymatous hypodermic injections, has suffered the same fate. Arsenite of copper has likewise failed in curing cancer. Other remedies have been used that have had many claims made in their favor, but up to this date, not one stands the test of experience. If any one agent were reliable in curing cancer, we would hear of no other means of treating it. Such a remedy the medical profession is looking for.

Pathology of cancer.—The cause of cancer was well known a few years ago, it was thought. Now, it is acknowledged to be one of the most thoroughly unknown subjects in the whole range of pathology. As late as 1890, the following was written by Pozzi in his monumental work entitled "Medical and Surgical Gynecology" (Vol. I, p. 333): "The great predisposition of the cervix to the development of cancer has been noticed by all observers. Is there anything in general anatomy which will explain the fact? Cohnheim has supposed that the embryonal cells which have not been absorbed in the function of the organs, and which are found scattered through the connective tissue or gathered in islands at certain points, may be the matrix tissue of carcinoma. These tumors are found most frequently in the nests of embryonal cells which define the natural orifices of the body, where there is more or less irregular involution of the blastodermic layers; the cervix uteri, developed relatively late, at the expense of the Müllerian ducts, belongs to this class of congenitally vulnerable points. The presence of two varieties of epithelium at the external os and the consequent plastic polymorphism which results, may also be a factor in their production. There remains unex-

plained, however, the exciting cause of the neoplasm. The repeated afflux upon which Cohnheim lays so much stress does not account for it."

This elaborate explanation of cancer only serves to show that our knowledge of its etiology at that time was absolutely negative. Ever since bacteriology came into our work, investigators have been busy in attempts at solving unknown problems in etiology. Within a few years it has revolutionized surgical pathology. It has illuminated many places that were formerly as dark as Erebus. The causes of many of the commonest diseases have been made as clear as the noonday sun. Many diseases are still baffling our bacteriologic researches. One of the most important of these unsolved etiologic problems is cancer. Occasionally, a glimmer of light seems to come, promising a full illumination of the subject. Scheuerlin thought his investigations cleared up the subject. In 1886, he isolated from cancers of the mamma a bacillus which, he asserted, is the active agent in the causation of cancer. It grows rapidly on blood serum, agar and gelatin, slowest on the last; and forms a red deposit on potato. Its spores stain only by the Ehrlich method in use for the tubercle bacillus, but the bacillus itself stains readily by ordinary means. He injected pure cultures into the mammary glands of dogs with the effect of inducing a hard tumor which, he states, is epithelial in its character. However, Koch and other Berlin bacteriologists are inclined to doubt its having to do with cancer, and look upon the morbid condition of the mamma set up as being simply a mastitis ("Text-Book of Pathology," D. J. Hamilton, Vol. I, p. 407).

Very many forms of bacteria have been found in the microscopic examinations of cancers. Their presence is accidental. They are not causative. That they are not the essential etiologic factor of cancer is shown by the fact that, when inoculated into healthy tissue they do not produce cancer. Other pathogenic bacteria whose history and disease-producing power have been verified repeatedly, will produce the diseases from which they are taken. To illustrate: Tuberculous bacilli introduced into healthy animals will produce tuberculous animals, which in turn will supply new bacilli that can produce tuberculosis in other animals. Thus many successive animals can be successfully rendered tuberculous from one original inoculation, proving incontestably that the bacteria of disease produce their kind. Many other diseases can be produced at will. Tuberculosis is not the only one. The horrible malignity of cancer has made it an object of especial interest to bacteriologists, for, if we can isolate and demonstrate the especial bacterium of this dread disease, we stand in an infinitely better position to find its cure.

In 1896 Kahane, who was the first to describe the presence of blastomycetes in malignant tumors in his last communication (*Centralbl. f. Allg. Path. und Pathol. Anat.*, June 15, 1896) states that the blastomycetes which he has constantly found in malignant growths is nothing more than the common yeast, *saccharomycetes cerevisiæ*, and he defines, tentatively, epithelioma (on which his statistics have chiefly been made) as the expression of a peculiar symbiosis of epithelial cells, leucocytes and *saccharomycetes*.

Roncagli studied five sarcomata, in all of which he found blastomycetes that resembled each other very much and were similar to those described by San-

felice, and by the author, as occurring in adenocarcinoma of the ovary. They take the specific stain of blastomycetes, and resist the action of acids and alkalis like those found in the adenocarcinoma of the ovary. The parasites may be found within and without the cells, exceptionally also in the nucleus; they multiply by budding, and may in the early stages, *i. e.*, when without membrane, possess an abundant chromatic protoplasm, or in the adult stage, *i. e.*, with membrane, may have but little chromatic protoplasm or a protoplasm that has entirely lost the power of staining with anilin dyes. (*Centralbl. f. Bakt. und Parasit.*, Oct. 26, 1895).

Sanfelice has made inoculations into guinea pigs, of a yeast which he terms *saccharomycetes ellipsoideus neoformans*. Animals that had received an inoculation into the subcutaneous tissue died, on an average, in thirty days. The inoculation was in a few days followed by a local swelling, which might or might not break down. The lymphatic glands of the groin and axilla also became enlarged. At the autopsy the tumor in the subcutaneous tissue was soft, not firmly adherent to the skin, and presented an appearance like that of the flesh of fish; the lymphatic glands had the same characters. The spleen was enlarged and was studded with elevated whitish nodules; the liver was but slightly increased in size, and rarely showed the whitish spots seen in the spleen. In the kidneys the nodules were more common than in the liver. The intestinal follicles and lymphatic glands were enlarged. The lungs were also enlarged and contained whitish areas. Brain, heart and adrenals showed no microscopic change. Guinea pigs that were inoculated into the testicle died in the course of twenty-five days. Testis and epididymis were enlarged and contained fish-flesh-like masses. Inoculation into the liver was followed by the development of tumors, single and multiple, in that organ. The changes were most marked after intra-abdominal inoculations. A severe peritonitis, which the author terms a neoplastic one, was always noted. The viscera also presented nodules as previously described. The nodules contained enormous masses of blastomycetes. Many leucocytes containing blastomycetes were seen. Histologically the tumors consist of a network of young connective tissue in the meshes of which a variable number of cells resembling lymph-corpuscles is seen. Parasites are so abundant as to constitute the greater part of the nodules. The majority of parasites lie free, and vary in their tingibility. The enlargement of the lymph glands depends more on the immense number of parasites present than on a proliferation of the cellular elements. The parasites could be demonstrated in nearly all the organs, but produced no reactive inflammation. The absence of epithelial hyperplasia in guinea pigs is explained on the ground that death occurs too soon for it to take place.

The author then proceeds to point out the striking similarity between the appearance of the blastomycetes in the tissues and the so-called coccidia described by many writers as occurring in the malignant tumors of man, and comes to the conclusion that the latter bodies are not protozoa, but blastomycetes, a view that had already been advanced by Russell. (*"American Year Book of Medicine and Surgery,"* 1897, p. 708).

At this point, I wish to make an extensive quotation from a reprint by Prof. R. Park of Buffalo on the

"Etiology of Cancer," just received from him. My work of looking up this topic had reached this point when his article appeared, most opportunely. The paragraphs quoted present to us the completest statement of our most advanced knowledge of this much studied topic: "The work of the Italians in this direction has been most creditable and apparently most convincing. It has been done for the most part by Prof. Sanfelice, of the University of Cagliari, in Sardinia, and Prof. Roncali, of the University surgical clinic in Rome. The former published his first paper on the subject in January, 1895, and the latter followed with his first only a month later. To these two men and their assistants we owe most of that which I shall epitomize below.

"As the work of these Italians points, with a high degree of probability, toward the blastomycetæ as the active agents, it will be worth while to stop for a moment and rehearse the most important facts known with regard to this class of fungi. It is best known as that to which the common yeast forms belong. These fungi reproduce themselves, not by division into halves, as do the common bacteria, but by the process of budding; the cells, when undergoing this process, appearing under the lens much like the common forms of cacti. Each bud provides itself with a membrane when separating from the parent cell, and thus becomes complete in itself. The parent cell does not die in this process, but gives rise to other buds, the entire process consuming about two hours in those forms where the life-history can be easily watched. This is slower cell division than occurs with the ordinary bacteria. The new cells thus produced are often bound together in clusters or irregular chains. Each cell has its proper membrane, which is filled with protoplasm, and contains a nucleus. It will average eight to ten millimeters in size. Under particularly favorable circumstances spore-formation may also take place, so that from two to ten endospores may be seen in one parent cell. These spores are less resistant than those of the common bacteria. They are killed by five minutes' exposure to 62-70 degrees C. Those blastomycetæ which are capable of spore-formation are the least hardy, living in the ground for about a year, while others can live, under the same conditions, for three years. This is worth remembering, because there is much reason to think that these fungi are introduced into the system from the most common sources and by the ordinary paths of infection.

"They will grow on media which are slightly or strongly acid, and by this means can be separated from many of the common bacteria. Each species has its own peculiarity as to behavior respecting the various sugars. For example, by an ordinary wine yeast 1000 grams of grape sugar were split up into 506 grams of alcohol and 30 grams of other products, including 21 grams of glycerin. (By the way, the taste of various wines is quite perceptibly influenced by the amount of glycerin present therein.) Alcohol fermentation can go on with or without access of air. If air be present, cell production is more active, and other cell activity is lessened and *vice versa*. Acetic fermentation and putrefaction are facultative aerobic actions.

"So far as pathogenic activities are concerned, blastomycetæ are known to be active disease agents in certain cases. They are commonly found in the urine of diabetic patients, but whether by accident or in some

other relation is not positively known. Numerous forms have been cultivated and inoculated, with resulting severe or even fatal symptoms, as in the morbid condition called saccharomycosis, which is known as an experimental disease. Thus it is established that a general infection from this cause is possible, and the question may arise whether general carcinomatosis is of this nature.

"Now, it is almost exclusively the blastomycetæ with which the Italians have worked, and have produced their remarkable experimental results, for they have found these organisms both within and between and around cancer cells, and have succeeded in making cultures in and upon acid media. Moreover, by inoculations with these cultures they have produced tumors in animals which bear the strongest possible resemblance to those neoplasms from which the cultures were originally made.

"These parasites must be sought for in the periphery of the tumors and in the juices of the same, but not in the central portions, for here they often seem to have disappeared. This is true both of sections for microscopic examination and of the portions which are taken for inoculation purposes. Furthermore, most of the experimental tumors thus produced have returned the same blastomycetæ upon further culture tests. Two or three different forms have been definitely named by their discoverers; thus Sanfelice has described a *saccharomycis lithogenes*, and Roncali a *blastomycis vitro-simile degenerans*. These names both call attention to the remarkable properties which some of these fungi possess, not only of undergoing rapid degeneration, but of displaying a peculiar calcareous deposit within the cell membrane, which is undoubtedly due to calcium carbonate, since when these are treated with 4 per cent. solution of hydrochloric acid the degeneration forms all disappear, while when treated with 4 per cent. sulphuric acid, crystals of calcium sulphate form. As showing also their marked tendency toward degeneration, Roncali placed two pieces of tumor in a Petri capsule and kept it 37 degrees C. for four days. In the juices the unde-generated forms were undoubtedly much more abundant than in the fresh specimens, which would indicate their truly parasitic nature.

"As an illustration of the method of securing cultures, he prepared in one case sixty tubes of distilled water containing a little sugar and acid; in each of them he placed small bits of tumor cut with a sterilized knife. These were kept at 37 degrees C. for ten days, when surface growths were found upon forty-seven of them, which, when examined in the hanging-drop, were easily recognized as blastomycetæ.

"Sanfelice has produced small tumors in numerous of the smaller animals by injection of his *saccharomycis* above alluded to. It is most interesting also that some of the blastomycetæ which he discovered in tumors were identical with those found upon the common lemon, which grows so abundantly upon Italian soil. Among other experiments he injected *saccharomycis* into the mammary gland of a bitch, which lived for fourteen months and then died with a definite tumor in the gland and with metastases in various organs. Also, after injecting this culture into the abdomens of guinea pigs, he saw them die in from twenty to forty days as the result of neoplastic lesions, while when injected beneath the skin, they killed the animals in from thirty to fifty days with local manifestations.

"Thus, without quoting in detail the experimental labors of Sanfelice, Roncali and their pupils, it may be stated as positively proven that the blastomycetæ above alluded to, *i. e.*, at least some of them, are capable, first, of being isolated by culture methods from certain carcinomata and sarcomata; second, of identification as belonging among the yeasts; third, of producing tumors in animals by injection under suitable precautions, the resulting tumors being strikingly analogous to or identical with those from which cultures were made; and fourth, of furnishing from these tumors further cultures, from which yet other experimental inoculations can be made.

"Without going so far as to say that this can be done in every instance, or that all cancers are necessarily of parasitic origin, one is justified by these results in at least maintaining that some cancers are positively of such origin. If upon this experimental ground, one should infer that all cancers are parasitic manifestations he would do, as will be seen, little violence to the laws of logic."

The foregoing quotation gives all that can be offered up to this writing on the latest investigations on this vexing question.

The agent used in the cases I herewith report is the carbid of calcium. Its name indicates its composition. M. H. Moissan first obtained, in 1894, a crystalline compound of carbon and calcium by employing the intense heat of his electric furnace whose temperature may approach 3500 degrees C. Its specific gravity is stated to be 2.262, the low figure being due to the fact that calcium is next to the alkali metals, one of the lightest of the metallic bodies. Exposed to the atmospheric air it is soon resolved into coarse powder-like sand. It is very refractory. A chisel and a hammer are necessary to reduce it to small pieces suitable for use in treating cancer. In the presence of water acetylene gas, the new illuminant, is instantly evolved. Upon dropping a fragment into a basin of water, one can ignite the escaping gas, which presents the apparent phenomenon of burning water.

The chemic formula of the carbid of calcium is CaC_2 . That of acetylene gas is C_2H_2 . It is liberated from the carbid of calcium by water. The equation representing this is $\text{CaC}_2 + \text{H}_2\text{O} = \text{C}_2\text{H}_2 + \text{CaO}$. A piece of the carbid of calcium can be thrown into a fiery furnace and it will not ignite. It can be fused and run into molds of any design without ignition. A piece can be held in a Bunsen burner without the least effect. But if a drop of water is put on the stony substance, it effervesces and the gas can be lighted and will burn like a piece of wood for a few seconds until the water is exhausted. Then it goes out.

Commercially, acetylene gas is very valuable. Discovered only five years ago, it has already become a most formidable rival of the old gas companies. It is rapidly being introduced as the illuminating agent in residences at a moderate expense. It is meeting with especial favor in small towns where no gas companies exist. Individual plants are set up in back yards where safety from explosions is secured, whence the gas is conveyed by proper piping to the houses, which are thus more brilliantly lighted, many times over, than by ordinary illuminating gas. It produces a singularly white, bright flame. Several jets of it can make the ordinary Edison incandescent coil appear like a red-hot hairpin. Many of the old time gas companies are adding a small proportion of acetylene gas to that used by them, with the effect of

giving their customers better light. So clear, steady and powerful is the light made by acetylene gas, it has been proposed to make it the standard for photometry. The numerous ways in which it is already used indicate the readiness with which its superiority is accredited. It is used in bicycle lamps. The oculist, aurist, and laryngologist are using it to illuminate the organs that they investigate. It is used in electrometers. It is used in lighting omnibuses. It is employed in the stereopticon and in photography. Microscopists and chemists in blow-piping, are employing it. It possesses a very low temperature of ignition. It can be solidified at a comparatively low pressure ("L'Acetilene e le sue Applicazioni." Published in Milan, Italy). When liquified, it passes into the state of snow, like carbonic acid. This snow, upon evaporating, lowers the temperature 180 degrees.

Acetylene, containing C and H, permits the curious fact that the proper amount of oxygen can be added to it to make pure alcohol. Commercially pure alcohol can thus be made at a cost of four cents per liter.

Acetylene gas is distinctly poisonous when administered to animals in a sufficiently concentrated form. Inhaled in the open air, it is but slightly harmful. The recent experiments of Grèhant, Berthelot and Moissan show that it is fatally poisonous when present in proportions as high as 40 per cent. by volume. One hundred volumes of air dissolve about eighty volumes of acetylene. If any compound of acetylene and hemoglobin is formed, it is very instable and is not analogous to carboxyhemoglobin (Brociner: *Boston Med. and Surg. Jour.*, July 30, 1896). One pint of pure acetylene given rapidly to dogs, guinea pigs and other animals caused severe symptoms of poisoning, but the animals recovered when placed in the open air. If given slowly, they did not recover when placed in the open air (Mosso and Ottolenghi: *Rif. Med.*, Jan. 23, 1897). Paralysis of the respiratory function is the toxic effect of this gas.

Recently many reports of explosions of acetylene have been made in current publications. Its explosive power is greater than that of ordinary illuminating gas, but it is not more dangerous when the ordinary precautions are taken. Brass should be avoided in pipes and burners intended for use with acetylene, since it unites with copper to form solid copper acetylene which explodes violently on percussion or on heating to 200 degrees C. Rosemann states positively that acetylene does not combine with hemoglobin (*Arch. f. exper. Path. u. Pharmacol.*, V. xxxi, p. 179). The poisonous action of acetylene, while admitted by all experimenters to exist, is now claimed to have been greatly exaggerated by earlier investigations because of the probable presence by impure gas (Grèhant, Berthelot, Moissan and Beocinet: "Comptes Rendus," 1896). Its odor is not unpleasant. To some people it is faintly aromatic. When the carbid of calcium is reduced to the pulverulent state, the gas can still be evolved and ignited.

In the fall of 1896, I first saw reference made to the use of the carbid of calcium in the treatment of uterine cancer in some medical journal. It was contained in about four lines, which stated that some German physician used it in treating cancer of the uterus. I have forgotten his name. I therefore distinctly disclaim all pretense to originality in its use.

Treatment.—After determining that I have to deal

with uterine carcinoma, the necrotic debris is thoroughly removed by curetting under anesthesia, till firm tissue is reached. Hemorrhage from arterial twigs is then checked by the use of the Paquelin cautery. Free irrigation with very hot water is then used to check the oozing, if necessary. It is desirable to have the seat of the operation as dry as possible before using the carbid. Into the cavity which extends to a greater or less extent up into the body of the uterus, a piece of the carbid about the size of the last phalanx of one's thumb, is placed. At once, acetylene gas is evolved which quickly fills the entire cavity with a froth, like soap-bubbles. The cavity is at once packed firmly with iodoform gauze. The vagina is packed full of the same material down to its ostium. The patient is then put to bed for three days, when the gauze and the carbid remains are removed and a new piece is used. The carbid remains are naught but a grayish clay covering the cavity in the body of the uterus. It can be sponged and irrigated away in a few minutes, dried by sponging and prepared thus for another application of the carbid. Upon depositing the carbid in the wound, we witness the same bubbling of gas as seen before. Gauze packing is then used and the patient is permitted to remain three days until the next dressing.

After a series of such applications of the dressings, the ragged, necrotic-faced ulcer is converted into a simple, clean ulcer. It presents a base covered to all appearances with pinkish-red granulations, destitute of the gray color which characterized its appearance after the second or third dressings. After a few treatments the edges of the cavity begin to draw in, and the area of the crater is diminished. Its entire appearance impresses one with the idea that it has taken on an entirely healthy character. Further persistence in its use is followed by progressive contraction till finally the cavity is entirely obliterated. There is a puckering of the vault of the vagina about the small uterine os that remains, the whole field being covered by healthy pink mucous membrane.

CASES TREATED.

Case 1.—Mrs. Y., aged 69 years. Her last child was born forty six years ago. She passed the menopause at 48 years of age. For twenty-one years she had no bloody vaginal discharge. On Dec. 14, 1896, she complained to me saying she had had menorrhagia for six months. At first, the bloody flow was only at intervals. At the time of her visit, it was continuous. Examination revealed about two-thirds of the cervix absent from carcinomatous ulceration. About one-third of the cervix remained uninvaded. Four days later, at the Presbyterian Hospital, I began to do a vaginal hysterectomy. A very careful examination under anesthesia revealed an invasion, as I interpreted it, of the right broad ligament with thickening and some degree of ankylosis of the uterus. All that was done was to curette very thoroughly and burn with the Paquelin cautery. A cavity was left fully two-thirds the size of an ordinary hen's egg. Into this I placed a piece of the carbid of calcium the size of the last joint of my little finger. I packed a large amount of iodoform gauze against the piece of carbid of calcium and filled the vagina with gauze. In a week, after leaving the first piece of carbid of calcium in four days, I repeated the treatment with this agent, leaving it in three days. After each treatment, upon the removal of the gauze, the wound was free from necrotic debris, hemorrhage and odor. The cavity left by the curetting was beginning to contract very rapidly. After the removal of each iodoform gauze packing, naught remained but sand. The third treatment was made ten days later with the same result, namely, the utter absence of hemorrhage, discharge of necrotic debris, odor, and the contracting of the cavity. These treatments were continued regularly till well along into May, 1897. The cavity produced by the curetting had entirely disappeared, the thickening in the right broad ligament had disappeared, and there had been no discharge nor hemorrhage.

I did not see the patient again until July 30, 1897. She was still without discharge or hemorrhage. I saw her again the first week in October, 1897, with exactly the same condition. I did not see her again until May, 1898. In the meantime, she had been remarkably well and strong, performing her accustomed duties that she had been used to for a quarter of a century. Her seventieth birthday was in January of this year. At her last visit in May, she informed me that she was having an occasional bloody, grumous discharge from the vagina, coming with a sort of gush as though the pent-up fluid, about a drachm in amount, was suddenly released. She said it had an odor like old fish, not like cancer. This discharge had been going on at intervals for a few days for about a month.

I am now waiting developments in her case. I do not pronounce the verdict in her case till at least two years have passed from the date of her operation. The vaginal examination, at her last visit, revealed exactly the condition of things that existed one year ago. The vault of the vagina was drawn together like the apex of a cone with an opening up through it, leading to what I take to be the remnant of the uterus. Not a particle of solution of continuity was visible.

I think the claim can be made that no other line of treatment known at the present time, would make a patient so comfortable and entirely free from the usual horrors of cancer for a space of a year and a half, as has been used upon this woman. While I make no pretense of calling this case one of cure of cancer of the uterus, yet I do claim for it what I have just mentioned.

Case 2.—Patient aged 53 years, had passed the climacteric seven years. The cervix was entirely absent through carcinomatous ulceration, which had left the body of the uterus a simple shell. She had had hemorrhages for five months before I saw her. She was emaciating rapidly and losing strength, and was generally septic. Her face presented the cancerous cachexia. After curetting away the necrotic debris, on July 30, 1897, naught was left of the uterus but its cortex. Treatment was precisely the same as in case No. 1. Similar results followed. After about five months the cavity of the ulceration had entirely disappeared by contraction. In February, 1898, she became very ill with a severe chill and pelvic pains. Relief came slowly under opiates and hot fomentations, and on the eleventh day an abscess suddenly discharged through the small opening in the vault of the vagina. She was up and around in a few days. Since then she has, to all appearances, fully regained her strength and color and has gained flesh. In the early part of May, of this year, examination revealed a total absence of any vaginal solution continuity. Nothing but pink healthy mucous membrane is visible. Since the beginning of treatment in July, 1897, there has been neither discharge, odor, nor hemorrhage. She is performing her customary duties just as she did eighteen months ago.

I have several other patients under observation who are receiving the carbid of calcium treatment. They are in varying stages of progress. No conclusions can yet be drawn from them. Concerning each one the remark may be made that they are free from discharge, hemorrhage and odor, and that the cavity is decreasing in size. Till the best way was learned to treat them, I did not always succeed in abolishing the odor.

As to the *modus medendi* of the carbid of calcium, I have no opinion. Bacteriologically, a series of experiments was made, both with the carbid of calcium and with acetylene gas, on several pathogenic bacteria, under the direction of Professor Hektoen, in the laboratory of Rush Medical College, with absolutely negative results. In a few cases an erysipela-

tous redness of the sound mucous membrane seemed to follow the use of the carbid, which would suggest that it resulted from an escharotic action of the acetylene gas. Whether the acetylene gas destroys the cancer cell by annihilative action, or by chemically changing it, remains to be seen. One thing seems to be certain, and that is that the carbid of calcium at least postpones death and makes carcinoma patients vastly more comfortable while they do live, than any treatment known to the writer.

31 Washington St.

CHRONIC PHLEBITIS OF THE SAPHENOUS VEINS; SAPHENECTOMY.

BY E. VIKO, M.D.

PARK CITY, UTAH.

The pathologic condition of chronic phlebitis is a sclerosis of the veins, similar to atheromatous changes in the arteries; the veins become cord-like. All the coats of the veins may be thickened and indurated, or the external coat only may be affected. In chronic phlebitis of the saphenous veins of the leg, the tissues around the veins are also swollen, often several times their natural size. Varices of the adjacent branches sometimes occur. In cases of long standing, eczema and ulcerated patches affect the skin, which becomes hard, thick and glazed. Severe pain, especially on standing or walking, is complained of.

Medicinal treatment of chronic phlebitis of the saphenous veins is very unsatisfactory. Drugs may ameliorate the eczema, pain and swelling to a certain extent, but this is only temporary.

Surgery promises better results. Lea recommends tying of the veins. The most rational method seems to be the removal of the veins. They have lost their function and act only as an irritant. No surgery to which I have access recommends removal of the saphenous veins for chronic phlebitis; but in view of the fact that their removal for varices effects the surest and speediest cure, I decided in one case to remove the internal saphenous vein for chronic phlebitis, with the happiest results.

Mrs. F., age 55 years, had been suffering for fourteen years with chronic phlebitis of the internal saphenous vein of the left leg. The limb was greatly swollen and walking or standing occasioned severe pains. A good part of the time she could not obtain the necessary sleep on account of the pain. The skin of the leg was covered with an intractable eczema. She had for several years used a variety of drugs, internally and externally, with very little result. I suggested the removal of the vein, and on Feb. 28, 1898, I cut down on the vein in front of the internal malleolus; it was considered easier to find the vein there than higher up on account of the swelling. The vein felt and looked like a tendon. The only way by which I could tell whether it was the vein or not was by pricking it. The tissues over the vein were then laid open to about an inch above the knee, where the vein seemed to be healthy. The swollen and indurated tissues over the vein were in most places about an inch and a half in thickness. The vein was tied in two places above the knee with No. 2 formalinized catgut and was severed between the ligatures. As the vein was dissected out downward, branches were tied with the same material. It was finally tied near the internal malleolus and removed. I was careful not to injure the internal saphenous nerve. The wound was

closed with No. 2 formalinized catgut and dressed with aseptic gauze and cotton. There was no rise of temperature at any time except on the second day, when the thermometer registered 99.5 degrees. The wound healed by primary union. All the swelling, induration and eczema have left the leg and she is now free from pain, the first time in fourteen years. Walking or standing does not cause any pain or swelling in the limb.

I have examined several surgical works, even of recent date, and find no mention of removal of the internal saphenous vein for chronic phlebitis.

These cases are frequently met with and the old treatment recommended is anything but satisfactory, while saphenectomy seems to be a sure and speedy remedy.

In my experience in varices of the internal saphenous vein removal is better than Phelps' operation.

SOCIETY PROCEEDINGS.

Delaware State Medical Society.

Meeting held in Wilmington, Del., June 14, 1898.

The meeting was opened by the President, Dr. P. W. TOMLINSON of Wilmington, who delivered an address entitled,

THE INTERESTS, OBJECTS AND BUSINESS OF OUR SOCIETY.

After commenting on the fact that the charter of this Society was only thirteen years younger than the Declaration of Independence he referred to some of the reasons why medical men did not take more interest in their annual medical meetings. He urged all to make known by writing and talking whatever new observations they may make of interest to medical men and considered a medical society the best means of conveyance for this information. He then dwelt at great length on the purposes of State medical societies in general and quoted fully from a number of letters received from other States, as to the results obtained by these societies in elevating the profession and killing quackery.

Dr. WILLARD SPRINGER read a paper entitled

SHORT HISTORY OF 1800 OBSTETRIC CASES.

The author divided this subject into eighteen groups of 100 each and mentioned one or two interesting cases in each group. He said concerning his management of cases: "If the case is an ordinary one and the labor well advanced and likely to be over soon after I first see it, I use the ordinary precaution of thoroughly washing my hands in hot water, but if the case is likely to be prolonged and to require many digital examinations or perhaps operative interference I use a bichlorid solution for my hands, carbolized vaselin as a lubricant and a solution of creolin for my instruments. Of course I occasionally have a case of septic infection and then, when the temperature is high and the lochia offensive, I use an intra-uterine douche of a mild bichlorid solution, 1 to 4000. Last winter I saw a case in another physician's practice in which the temperature was above 106 degrees just before the douche was given. The next morning it was down to 103 degrees and never went so high again, but the woman made a slow recovery on account of an attack of puerperal mania. I have great confidence in antiseptic and aseptic precautions in operations of all kinds, but I do not see that I have any fewer deaths in my obstetric practice now than I did in the early years when such precautions were unknown.

Dr. JOHN PALMER of Wilmington, gave the details of a case briefly referred to by Dr. Springer, in which the instruments were applied for five or six hours and the brain of the child squeezed out of the head before it was delivered, the mother making a good recovery.

Dr. JOSEPHINE WHITE asked how often Dr. Springer had administered anesthetics in the first stage of labor in his 1800 cases and in how many cases the temperature went above normal. She also commented on the indifference displayed by the better and upper middle classes toward absolute cleanliness in obstetric work and did not believe that the possibility of post-partem hemorrhage was a contra-indication to the administration of an anesthetic.

Dr. W. H. HANCKER of Farnhurst, Del., detailed a case of delirium following septicemia in which the emptying of the uterus was followed by death in two days.

Dr. H. J. STUBBS of Wilmington, inquired how often the author had used anesthesia in his large experience and also how soon he would advise curetting.

Dr. JONES believed that the sooner the uterus is emptied the better so as to prevent the absorption of germs. He advised that great care be taken in performing the operation, not to bruise any more surface than was absolutely necessary as these abrasions all acted as avenues for the absorption of septic material. For the purpose of sterilizing the instruments as well as washing out the uterus he strongly recommended a solution of lysol, for the latter purpose using a strength of 1 per cent.

Dr. SPRINGER closed by stating that he gave anesthetics whenever he deemed it necessary, considering each case a law unto itself. He admitted employing them more frequently of late years for three reasons: 1. That the method is more common than it used to be; 2, the different class of people composing his practice of late years, and 3, because people are becoming more educated to the use of anesthesia. He believed that frequently anesthetics prolonged labor and made the patient feel worse afterward and reported having known cases where it had been declined after the first administration. Although occasionally using ether his preference was for chloroform, but he had never found it necessary to use either in the first stage of labor. Referring to the question of douching he stated that he did not make a practice of doing so before labor and not even after labor if it had been a natural one without many digital examinations and without the use of forceps. When douching became necessary he preferred to use bichlorid 1 to 3000, always washing this out with a boric acid solution.

As to the removal of the placenta the author's method after cutting the cord is to place one hand upon the abdomen and with the other use slight traction on the cord. He did not think that breaking the cord was a serious matter, but rather thought it was good for it to bleed somewhat. In his opinion, when difficulty is experienced in removing the placenta, it is due to the fact that the whole bulk comes down right over the os and renders it difficult to compress it sufficiently to pull it through.

Dr. E. S. DWIGHT of Smyrna, Del., read a paper, entitled
POST-PARTUM HEMORRHAGE WITH UTERINE CONTRACTION.

After briefly describing the usual termination of a normal labor he referred to the premonitory symptoms of post-partum hemorrhage and to the sources from which this hemorrhage may come, mentioning among others, laceration of the perineum due to the passage of the head or more probably the birth of the posterior shoulder, a wound of one or other vestibular bulb, a tear of the vaginal wall, or a laceration of the cervix with the tearing of an arterial branch. He then gave details of four cases of post-partum hemorrhage all of which he had treated successfully by the applications of tampons. He referred briefly to other more recent and more scientific methods but pointed out the great difficulty of their application in a country practice, especially at night time.

Dr. CHARLES P. NOBLE of Philadelphia believed that the hemorrhage in most of these cases came from the vestibule, particularly when the baby had been delivered with forceps. He agreed with the author of the paper that the method of treating these hemorrhages must depend upon the facilities and experience of the individual in attendance, but strongly advised suturing whenever possible. Among other objections to the emergency tampon he mentioned that they were a great source of infection.

AFTERNOON SESSION.

Dr. BRIGGS reported a case of carcinoma in a six weeks pregnant uterus and showed the specimen removed with the fetus *in situ*, surrounded by a miniature bag of waters.

Dr. FRANK SPRINGER read a paper entitled

A CASE OF CAESAREAN SECTION.

The case occurred in a colored woman, aged 25 years, forty-seven inches high, with a small contracted pelvis and very much deformed lower extremities, that is to say, a marked case of rickets. The patient had been in labor seven days when first seen, and the pelvic diameter was so small that it was impossible to deliver her or even save her life except by performing laparotomy. This was done through an incision extending from the umbilicus to within two inches of the pubis, and a living female child was removed. The wound of the uterus was closed with catgut ligatures, while the abdominal wound was brought together by silk ligatures. The patient made an uneventful recovery, the wound being dressed once a day, the vagina douched twice a day, and turpentine and quinin being given for a few days. Four weeks from the time of the operation the patient washed her child, which, however, died shortly after the mother left the hospital.

Dr. CHARLES P. NOBLE of Philadelphia believed that Caesarean section was no more serious than any other abdominal operation if done at the right time, in the proper way, by a competent person and in suitable cases, and mentioned that the average mortality in Germany was scarcely more than 5 per cent. He referred to the fact that Sanger had done twenty-five of these operations without a death, Olshausen twenty-seven with two deaths, and Leopold fifty with one death, while the percentage of mortality in the United States is 40 per cent., principally due to the fact that the operation is badly done and is rarely performed except as a last resort. He also partially accounted for this mortality by stating that the profession in this country neglects to study the cases beforehand sufficiently to know when to interfere. He referred to the recent article by Dr. Reynold of Boston, reporting twenty-seven of these operations done by surgeons in the Boston Lying-in Hospital without a death, thus illustrating that just as good results can be gotten here as abroad if the cases are properly studied. He believed if these cases were brought to the surgeon sooner so that the operation could be done at the right time, and if physicians would learn to study more closely cases of pelvic deformity, the mortality would be brought down where it belongs.

Dr. H. M. THOMPSON of Wilmington, read a paper entitled
OBSERVATIONS IN GYNECOLOGY DURING FOUR YEARS' SERVICE
AT THE DELAWARE HOSPITAL.

He stated that more than 40 per cent. of the cases coming to the Dispensary complained either of simple or specific inflammation of the uterus or pelvic organs, the remainder being made up of displacements, lacerations, neoplasms, etc. In taking up the question of the advisability of making vaginal examinations of young girls the author hoped that the rule of every conscientious physician would be never to do so unless the history of the case indicated the definite existence of local disease. Chronic metritis was stated to be complained of by ten out of every fifteen women who applied to the dispensaries for relief, and the causes for this condition were inflammatory and non-inflammatory. Although the prognosis of these cases is often hopeless, yet at times much relief has been afforded by treatment, which was divided into medical and surgical, and the medical believed to be more valuable, consisting of hot vaginal douches and tampons, with rest and tonics combined at times with vaginal irrigation. While not speaking very strongly in favor of the curette he reported having obtained good results from this method in some cases. Intra-uterine medication was recommended in conjunction with the hot douches and tampons in suitable cases. Operative interference was referred to, but conservatism was advised in this direction. The paper closed with the histories of a few of the cases which illustrated points referred to in the paper.

Dr. H. J. STUBBS of Wilmington read a paper entitled

ABUSE OF CHARITY.

In referring to the growth of this abuse the author said: "It is not only an injustice to the older men, but a crying shame to the younger, that they are graduated by the hundreds from the various medical colleges with the just expectation of remuneration, and on the day they start practice they find the patients, they should expect, going to, and being treated by, the colleges from which they graduated."

The great difficulty was pointed out of ascertaining as to the rights of each individual to ask free medical advice at a hospital, and the results of such methods of treatment on the profession at large. Two methods were suggested to improve this condition: 1, that the family physician, when sending a patient to a hospital, should let the hospital physician or surgeon know positively of the financial position of the patient, and 2, the hospital physician or surgeon should be extremely careful to ascertain the circumstances of those that come without recommendation. Quoting Dr. Charles B. Burnett of Philadelphia, it was stated "last of all, and not least, the improper bestowal of medical charity pauperizes the recipients, the number of whom is now so large as to practically pauperize a large percentage of the community: . . . medical charity may be abused by the giver as well as by the receiver." Also quoting Dr. Frederick C. Shattuck of Boston: "medical charity in hospital dispensaries should be freely extended to those who require it and denied to those who do not."

Dr. JUDSON DALAND of Philadelphia stated that the average dispensary patient was inclined to view the advice received rather as something they could compel the physician to give than as an act of charity, and urged the necessity of a uniform course of action by all physicians. He attached very little importance to the truth of the average patient's remark that they could not afford to pay for medical advice, and re-

ferred to a method practiced by one institution in Philadelphia of sending people to visit the homes of patients and ascertain the exact state of affairs.

Dr. W. S. HAINES read a paper entitled

BURN OF SCALP WITH LOSS OF CALVARIUM, FOLLOWED BY RECOVERY.

The case occurred in a boy aged seven months, who was thrown into the fire-place by a larger brother, his head coming in contact with the fire. The burned surface was greased with various remedies, and bromids and morphin were given to relieve the pain and spasm. The soft parts sloughed off and subsequently considerable of the bone came away, leaving the brain exposed. Skin-grafting was unsuccessful and for some years past the open space in the skull, measuring about two and a half by four inches, has merely been covered with absorbent cotton or soft muslin, smeared with zinc ointment. The patient is now six and a half years old, and is having slight convulsions once or twice a month, although he is large and active and his intellect unimpaired.

Dr. J. A. ELLEGOOD read a paper on "Foreign Bodies in the Eye," and mentioned various methods for their removal.

The following officers were elected for the ensuing year: President, Robert Ellegood of Kent Co.; first vice-president, Dr. Robinson; second vice-president, W. H. Hancker of Farnhurst; secretary, Frank T. Belville of Delaware City; assistant secretary, John Palmer of Wilmington; treasurer, Wm. C. Pierce of Wilmington.

The next place of meeting will be Wilmington, at a date to be named later.

Minnesota State Medical Society.

Thirtieth Annual Meeting, St. Paul, June 15, 16 and 17, 1898.

FIRST DAY—MORNING SESSION.

The meeting was called to order by the President, JOHN F. FULTON.

Invocation, Rev. JOHN PAUL EGBERT of St. Paul.

The roll call and reading of minutes was dispensed with.

The report of the Treasurer, R. J. HILL, showed a balance in the treasury, after all expenses had been paid, of \$667.15. The report was adopted.

The Executive committee reported that all members of the society were invited by the Ramsey County Medical Society to attend a banquet at the Merchants Hotel on Thursday evening.

The Secretary read a communication from the chairman of the Rush Monument Committee, requesting that some action be taken in regard to raising funds for the Rush monument; laid on the table until following day.

The subject of the President's address was

IMPROVEMENTS IN MODERN METHODS OF TEACHING.

He believes medical men should take great interest in modern methods of instruction; that antique methods of set lectures have happily given away to more modern methods of demonstration; that this great progress has practically wiped out all schools, leaving but one school, viz., medical science. He said that while we have in a few States, notably New York, two societies, measures have been taken to correct this and leave but one society in each State, and that one united for the best and highest good of the profession. He then dealt with the history of medical teaching and said, all teaching should have for its highest aim the benefit of humanity. He did not wish to underrate or ignore theoretic teaching, but thought theoretic should be subservient to practical, and that the most important of all teaching is the ability to make correct diagnoses. One of the greatest advances in this direction is in the making of accurate records. This has been favored very much by the use of the microscope and improvements in chemic analysis. Anyone to be successful must be accurate, for inaccurate work is always unreliable and worthless. A source of congratulation is that in many States examinations are now protected by the strong arm of the law and nearly everywhere are required to be thorough, searching and based upon a thorough preliminary education. This is as it should be, for it is undesirable to have a doctor of indifferent general attainments. The doctor's education should be broad and consist of much general information outside of medicine, for anyone who is only educated in one line becomes narrow even in the subject in which he is supposed to be best informed.

Adjournment was then taken until 3 P.M.

FIRST DAY—AFTERNOON SESSION.

In the Section on Practice of Medicine Dr. GENTLES of Chicago presented a paper on

TREATMENT OF PNEUMONIA BY COLD.

He said the use of the cold bath had been given up on

account of the danger of shock and syncope. The gradual cold bath had also been abandoned on account of requiring absolute assistance, as the patient must not make any effort. He advocated the use of ice bags locally, filled first with ice water and later by chipped ice. They should be light and thin, so as to be easily applied and well borne. He claimed the red corpuscles would be increased by the application of cold. In delirium, cold sponging would reduce the temperature. A part of the body only should be exposed at one time and the part well rubbed. Cold in pneumonia must not be applied too suddenly.

Dr. HUNTER said we might as well admit we had no special treatment for pneumonia. He had not seen cases modified much by treatment and, on the other hand, had seen cases get well almost in spite of treatment. The most we can do is to keep up the patient's strength until the disease runs its course. He has used digitalis, but does not believe it to be a specific or an abortant, and he thinks we have no remedy equal to cold, but it should not be used for the purpose of shock and not be continuous.

Dr. ABBOTT said that we have a localized inflammation in pneumonia, very unlike typhoid or similar fevers. He knows of no remedy equal to cold, but he uses Leiter's coil in preference to ice bags, having found that ice bags would get full of air and not lie smoothly on the surface. If used they must be kept free from air, a very difficult thing to do. He would keep up cold continuously.

Dr. ANDREWS thought the danger was not from high temperature and concluded the cold treatment was irrational. He believes the danger is in the temperature going below normal, and does not believe in the use of cold.

Dr. THOMAS thought the pyrexia was the result of reaction rather than toxin.

Dr. GENTLES, in conclusion, said that bad results depended rather on the amount of excretion than on toxemia.

Dr. RAMSEY of St. Paul then presented a supposed case of

MYXEDEMA.

The patient was a German aged 44 years and mother of ten children, the youngest 3 years old. She is now in the menopause; five years ago began to grow fleshy and weak mentally and physically; has pain in right shoulder; feels tired, sleepy, nervous and apprehensive; perspires a little; urinates without control and frequently. The urine is normal in every respect. Temperature normal. There is a deposit over the entire body; lips thick, hands and ankles enlarged but no pitting on pressure; skin thickened; eyes expressionless; hair falling out; has been taking 5 grains of thyroid extract three times a day for three weeks with no improvement. The patient was examined by many of those present and much interest manifested.

Dr. CRAFTS presented a paper on

MEDICAL EDUCATION.

He reviewed the advances of the last twenty years and expressed great satisfaction at the higher degree attained by the medical graduate of today over former times. He thought the working of the law in many cases unfair, e. g., when a man who had perfectly qualified himself was not allowed to write a prescription until he had a certificate from the State Board, while a quack could advertise and practice under the very eyes of the officers with perfect impunity and safety.

Dr. SWEENEY, in discussion, thought these cases should be prosecuted by the local doctors, and stated that the Board of Examiners had no power to prosecute.

The general trend of the discussion seemed to be in the line of a national control of medical practice and qualifications and that after we had a health officer in the Cabinet, a uniform management of these things would be an easy step.

SECOND DAY—MORNING SESSION.

Dr. WALLING presented a report on "Antitoxin in Diphtheria." The report was accepted and the committee discharged.

His Excellency, DAVID M. CLOUGH, governor of Minnesota, and Mayor KEIFER of St. Paul were introduced and made brief addresses.

The following were admitted to membership in the Society: H. H. Witherstine, W. A. Dennis, W. A. Darling, A. F. Strickler, U. G. Williams, Henry Cotton, Chester M. Conlan, R. V. Earl, C. W. Moore, R. J. Sewall, Joseph A. Smeadlie, Charles F. Dewey, M. H. Reynolds, R. R. Stover, C. A. Smith, C. S. Reimstead, J. R. Pederson, F. A. Knights, G. E. Sinkler, G. J. Tweedy, Charles Genuo, A. S. Flemming, T. E. W. V. Appleby, C. P. Robbins, Ralph Peters, E. E. Harrison, C. D. Huntington, C. P. Robbins and A. F. Munroe. Prof. John V. Shoemaker of Philadelphia was, by unani-

mous vote, invited to deliver an address at the next annual meeting.

In the Section on Practice of Medicine Dr. WALLING presented a report of two cases of appendicitis treated by calomel and high injections, and Dr. HATCH read a paper on "Appendicitis from the Standpoint of the General Practitioner."

The general consensus of opinion in the papers and the discussion which followed favored an early operation where there was no general glandular infection and when the surroundings would warrant opening the abdominal cavity. Other papers in this Section were: "The Value of the Diazo Reaction in the Early Diagnosis of Typhoid Fever," "Widal's Test," "Lead Poisoning from an Unusual Source" and "Induced Abortion, Sepsis Anurea During Eleven Days; Death."

SECOND DAY—AFTERNOON SESSION.

Dr. JOHN T. ROGERS presented a paper on

CONTUSIONS OF THE ABDOMEN AND THEIR SURGICAL TREATMENT.

He said contusions resulted from kicks, blows and being caught between two solid substances as by logs, etc. There might be death without visible injury to the walls or, in some cases, any appreciable injury to abdominal contents. The chief symptoms were pallor, lividity, vomiting, tympanites. A contusion might injure any of the contents of the abdomen. The pulse and temperature could not be depended on for diagnosis, but were useful in prognosis. A small hard pulse and subnormal temperature being indications of fatality. Where abdominal contents are ruptured 96 per cent. of the cases die. He favors an early operation and believes it better to open the abdomen and find nothing wrong than to wait and take many chances. Rupture of the kidney is not as serious as rupture of other organs, since it may be removed and the function performed by the other.

Dr. MAYO has seen many cases and believes the greatest trouble is that they never recover from the shock and thus render an operation nearly impossible. He saw one boy who was run over by a wagon, who afterward developed ascites; a quantity of bile-colored fluid was drawn off and he recovered.

Prof. J. B. MURPHY of Chicago said the time for operation was important, but could not be given with exactness. When there is pain without cessation and nausea, it is best to operate. Inflammations following this character of injuries are much more fatal than other infectious inflammations, but he could not tell why.

Dr. McLAREN favors an early exploration to determine the nature of the injury. He reported a case of rupture of the gall bladder by contusion. The inflammation developed slowly and death resulted in three days. The postmortem showed the patient had a large gall bladder with numerous gall stones and he believes that if an operation had been made early the chances would have been favorable.

Dr. MAYO presented a paper on "Abscess of the Lung." Dr. MURPHY of Chicago in discussing this paper gave his ideas of treatment of cavities in the lung by rest procured by filling the pleural cavity with gas, as advanced at the late meeting of the AMERICAN MEDICAL ASSOCIATION at Denver.

Many were the patriotic and witty responses to the toasts at the banquet tendered by the Ramsey County Medical Society in the evening.

The response to "Remember the Maine," by the president of the Society, Dr. JOHN F. FULTON, was particularly apt and patriotic.

D. PARK RITCHIE exceeded himself in an overflow of dry humor in his response to "The Fallacious Doctrine of Malthus."

THIRD DAY—MORNING SESSION.

The next meeting of the Society is to be held at Minneapolis, June 21, 1899.

Election of officers resulted in: President, F. A. DUNSMOOR; first vice-president, A. T. COULEY; second vice-president, Mary Whetstone; third vice president, John Williams; secretary, William Davis; treasurer, R. J. Hill.

THIRD DAY—AFTERNOON SESSION.

The Section on Obstetrics and Diseases of Children convened at 2 P.M.

Dr. W. T. ADAMS, chairman of the Section, presented a paper on "Injuries to the Cervix Uteri." He thinks one more cause for laceration should be added to those usually enumerated by authors, and that is, that the anterior segment being unsupported by the walls of the vagina, is often pushed forward to a great degree, rendering a lateral rupture much more liable.

Dr. R. E. CUTTS, in a paper on

CAUSES OF MATERNAL DYSTOCIA,

Thought two causes were too much forward inclination of the

plane of the superior strait and lordosis of lumbar vertebra, either one throwing much of the expulsive force on the pubes. He also deplored the meagerness of clinical instruction in that the student is merely permitted to see and attend cases without a special instructor.

Dr. ERDMAN thought that whenever possible an examination should be made previous to labor and all probable or possible causes of dystocia should be known. He says students are not allowed to do this as much as they should be.

S. W. RAUSON of Dodge Center, in a paper on

CARE OF PREMATURE AND FEEBLE INFANTS

Said, too little was done to save the great army of such children born annually. Many may be saved by proper feeding and protection from drafts. The latter may be accomplished in absence of more perfect apparatus by placing in cotton near a coal stove or over a lamp where a constant temperature may be maintained. The temperature must always be indicated by a thermometer at the head and be at first from 99 to 100 degrees. The best food is mother's milk, next a wet nurse, and next cow's milk properly diluted and prepared.

Dr. COOL suggested that the reason a wet nurse was not the best was because the milk was not properly constituted; the colostrum necessary to act on the bowels of the child is not present.

Dr. WHETSTONE said the first bath should always be omitted and the child oiled instead; if this were always done she thought the mortality would be greatly diminished.

The Denver and Arapahoe Medical Society.

Meeting held at Denver, Colo., April 25, 1898.

POTT'S DISEASE

Was the subject of the symposium. Dr. J. T. ESKRIDGE opened the discussion by reading a paper on the diagnosis of Caries of the Spine. He said: I regard what is commonly known as caries of the spine, or Pott's disease, as a tuberculous inflammation of the various structures that compose the spinal column, and shall endeavor to differentiate it from numerous affections of these structures that are, in all probability, non-tuberculous in their nature.

Until recently an account of caries of the spine could be found only in works devoted to surgical subjects. So far as my information goes, Gowers is one of the first writers on the diseases of the nervous system, to devote in his work a lengthy discussion of this subject. The symptoms of the diseases of the spine should be as well understood by the physician as the surgeon, because a failure to examine for these, and to appreciate their importance in an early stage of the disease, may result in irreparable damage before the surgeon is consulted.

Causes.—Caries of the spine, in proportion to the number of inhabitants, is more frequent in Colorado than in the eastern and southern portions of this country. There are two reasons for the comparative frequency of the disease among us. One is that a larger proportion of our population follow dangerous occupations, especially mining, in which the laborer is more subjected to injuries of the spine than are those who live in agricultural and manufacturing districts. The second is, that a large number of those who reside in Colorado are suffering from chronic tuberculosis. Tuberculosis and traumatism to the spine are the two principal causes that result in caries of the bones of the spinal column. In regard to sex, the cases which I observed in adults in Colorado show that males suffer about four times more frequently than females. Before the 15th year my cases show a slight preponderance of the disease in the female. Caries of the spine is common in childhood after the third year, and next in young adults; but in Colorado we find an exception to this rule, as adults from the 20th to the 45th year are by far the most frequent sufferers. It does not seem to me that children in Colorado are afflicted more frequently with the disease than what is found in eastern portions of the country, this too, in the face of the fact that a larger proportion of the children in Colorado have tuberculous parents. Old age is not exempt from the disease. I have met with it in a woman in her 65th year, and in a man aged 67. The disease has occurred as early as in the fifteenth month.

Caries may follow injuries to the back in which the bones have not been directly injured, but inflammation may extend to the periosteum and bone substance from torn and inflamed ligaments. Caries of the spine following traumatism that has not fractured the bones may come on several months after the receipt of the injury, and in some instances after all symptoms of the injury have passed away. Syphilis plays an uncertain role in the causation of caries of the spine. Adjacent inflam-

mation, abscess, and blood poisoning may give rise to disease of the vertebrae.

Location.—The dorsal, cervical and lumbar regions of the spine, in order named, are most frequently the seat of caries.

The symptoms of caries of the spine may be divided into general and local. The former are most commonly seen in children. They consist of an appearance of declining health. The child is pale, anemic, feeble, the appetite poor and the bowels irregular. Flesh is lost, strength is lessened and the gait resembles very much that of a feeble, tottering old man. The step is short, slow, the foot is carefully placed on the ground, the ball of the foot bearing most of the weight of the body; the legs are slightly bent at the knees, the body is thrown forward at the hips, and while the spine is slightly bent forward at the cervico-dorsal junction, the back of the head is thrown backward, and in consequence, the chin projects well forward. The gait might be classed among the local symptoms of the disease. I have chosen to speak of it under the general, as it is only typically seen in children, and usually in those who present well-marked constitutional symptoms of impaired health.

Local symptoms.—These may, for the sake of convenience of study, be divided into bone, nerve-root and cord symptoms.

Bone symptoms.—Judging from my own experience, the earliest and most important symptoms of caries of the spine in the adult, and in many children, are localized pain, tenderness and muscular rigidity. The pain in the spine is felt at the affected part. I have never seen a case in which active caries affected two regions of the spine at the same time, and in consequence I have never met with a case in which there were two seats of pain in the spine from caries at the same time. In fact, when the pain has a long vertical extent, or when two regions of the spine are the seats of pain, the indications are against, rather than in favor of caries, or any other organic disease of the bones. The pain may be increased by jarring or rotating the spinal column, by quickly bending the spine backward or forward or from side to side, and especially by firm pressure over the diseased bones. It is among the earliest objective symptoms, and is probably the most constant. When the disease is situated in the most movable portion of the spine, as in the cervical region, movements of the spinal column, both voluntary and forced, are the most painful. The patient instinctively fixes the head in an abnormal position. Sometimes it may incline to one side so persistently as to simulate torticollis, but the sterno-cleido-mastoid muscle is tense on the side toward which the head is inclined, just the opposite of what we find in the latter disease. I have seen a few cases with apparently considerable thickening of the spines in the dorso-lumbar region following injuries to this portion of the spinal column. Marked deformity is often absent when the morbid process occurs in the cervical region until the disease has made considerable progress. A person, either a child or an adult, who can jump from a low chair down on the floor and light on his feet without experiencing considerable discomfort in the spine is probably not suffering from an inflammatory condition of the spine. An easier and safer test than the one just referred to, is to get the patient to jump from the floor and light on his heels. This will usually cause pain in the spine if caries is present. So far, I have met with only one case of unilateral caries of the spine in which the symptoms were distinctly unilateral for a period of several months.

Nerve-root symptoms.—Nerve-root symptoms may be divided into four classes: sensory, motor, reflex and trophic. The earliest of these, as a rule, are the sensory. When the disease is high up in the cervical region, the pain extends over the posterior portion of the head; in the cervico-dorsal, the arms suffer, and when the lumbo-sacral is the seat of the morbid process the pain may be felt along the course of the sciatic nerves. When the pains are first felt, the skin over the area to which the affected nerves are distributed is hyperesthetic, but later irregular areas of partial or complete anesthesia are present. Muscular rigidity from irritation of the nerve-roots is not an early symptom. The deep reflexes of the legs are probably not affected in caries of the upper two-thirds of the spinal column unless the cord is affected. I have seen a number of cases in which the plantar reflexes were greatly increased, and others in which they were normal or lessened before the disease had made much apparent progress. Trophic disturbances are seen only occasionally early in the course of caries of the spine. According to my experience, herpes zoster, occurring along the course of the irritated spinal nerves, is a very infrequent affection from bone disease.

Cord symptoms.—Are very frequent; they occur after the bone disease has made considerable progress. The mode of onset of cord symptoms varies greatly in different cases. They may come on slowly and require months or a year or more to

reach their height. In a few cases complete paralysis, especially of the legs, has developed suddenly. One case under my care some years ago, one leg was almost completely paralyzed six months before the other was perceptibly affected. The cord symptoms are motor, sensory, ataxic, reflex and trophic. It is not uncommon to have almost complete muscular paralysis of the parts below the lesion with sensory phenomena intact. If the lesion is high up in the cervical region so that the arms are not involved by damage to the nerves that supply them, the legs may be paralyzed before the arms. When the bone disease is on the level of the origin of the nerves that supply the arms, the latter will be affected by paralysis and wasting before the legs exhibit much impairment of motion. In caries of the spine affecting the lumbar enlargement of the cord, facial paralysis, muscular wasting and other pronounced trophic disturbances, with abolition of the reflexes of the legs, will be found. I have in two such cases obtained ankle-clonus, although there was no vestige of the knee-jerks. I have seen several cases of caries of the spine that had been mistaken for locomotor ataxia on account of the marked degree of muscular inco-ordination, together with shooting pains present. Persistent loss of voluntary control over the sphincters of the bladder and bowel in caries of the cervical or upper three-fourths of the dorsal region indicate a severe lesion to the cord.

Diagnosis.—Pain in a limited region of the spinal column, increased often by extreme lateral, forward and backward flexions of the spine; rigidity of the muscles that fix the bones at the affected part of the spinal column; the presence of tuberculosis, the history of injury to the spine or of tuberculosis in the family; areas of hyperesthesia, anesthesia; muscular wasting in arms; rigidity or flaccidity of the muscles of the legs. When evidences of bone disease precede cord symptoms, a diagnosis of caries, with sequential nervous lesions, will rarely be wrong.

Primary pachymeningitis gives rise to nerve-root and cord symptoms similar to those following caries of the spine. The absence of the positive evidences of bone disease and the diffuse character of the nerve-root symptoms would be in favor of primary pachymeningitis. The absence of such causes of pachymeningitis as syphilis, alcoholism and repeated exposure to cold, is in favor of caries.

Progressive muscular atrophy. The irregular distribution of the muscular atrophy in caries, the severe jams along the course of the spinal nerves injured as they emerge through the diseased vertebrae, and the presence of areas of hyperesthesia or anesthesia, with perhaps local evidence of bone disease, such as pain and tenderness in a limited portion of the cervical spine and rigidity of the posterior cervical muscles, would serve to distinguish caries from progressive muscular atrophy.

Spinal irritation.—In spinal irritation there are usually two or more areas of considerable vertical extent of spinal tenderness. In spinal irritation deep pressure does not increase the pain over that produced by slight pressure. I am not prepared to accept Dr. Gibney's statement that "in Pott's disease, particularly in children, there is very rarely tenderness over the spinous processes." I can not recall a single case of caries in the early stage in the adult in which the spinous processes of the affected vertebrae were not somewhat sensitive to firm pressure and forcible lateral movements of the spine.

Hysterical paraplegia.—The presence of distinct evidence of bone disease in the vast majority of such cases, and the undeniable proof of an organic lesion of the cord, will be found if carefully searched for and should prevent such a mistake.

Sciatica.—When only one sciatic nerve is involved in caries beginning unilaterally, an error in diagnosis may occur. It can, as a rule, be prevented if it is remembered that in neuritis due to pressure the nerve below the seat of pressure, while it may be the seat of pain, is not tender until sufficient time has elapsed for descending neuritis to affect the peripheral portion of the nerve.

Torticollis.—A mistake in diagnosis may usually be prevented if it is remembered that in torticollis, the head is fixed by muscular contraction, and the face and head are turned to the side opposite that of the tense sterno-cleido-mastoid muscle, while in caries this muscle is tense on the side toward which the head is turned, this muscle being simply stretched on account of the fixation of the head from bone disease.

Neuralgia.—In all cases of supposed neuralgia of the fifth cranial nerves and of the spinal nerves, the spine should be carefully examined.

Syphilis.—I have never seen a case of disease of the spinal column in which I could, with any degree of confidence, make a diagnosis of syphilis, neither am I able to learn from the literature on the subject any reliable diagnostic symptoms, by the presence of which syphilitic lesion of the spinal column may be diagnosticated. We must remember, however, that it

is sometimes impossible to distinguish between a tubercular and syphilitic dactylitis. A patient, a colored woman, has been in the Arapahoe County Hospital for a period of about two and one-half years, whose whole dorsal region is arched forward, with shoulders and hips thrown backward. There has been no tenderness of spines, no positive evidence of disease of any of the vertebrae and no symptoms of spinal cord or nerve-root lesion. The deformity is gradual, not acute, and involves six or eight vertebrae. The muscles of almost the entire dorsal and lumbar regions appear to the touch nearly as hard as wood, and are not tender under firm pressure. Her condition does not appear nearly as desperate as it did at the time of her admission into the hospital. She made considerable improvement at one time under large doses of potassium iodid and inunctions of blue ointment.

Rheumatism.—If the rheumatism attacks the joints of the spine there is said to be no pain caused by jarring the spine, as in walking or by crowding the vertebrae on themselves in vertical pressure. I am inclined to think that this test of Ransom is unreliable. In case deformity of the spine takes place from rheumatism, the kyphosis involves several vertebrae and is less acute than in caries from tuberculosis.

Gonorrhea of the spine.—I have had no personal experience with gonorrhea of the spine. The most reliable points in the diagnosis are the presence or gonorrheal rheumatism in other portions of the body and great tenderness of the spine.

Typhoid spine.—I published some years ago a clinical lecture which I delivered at the Arapahoe County Hospital, on a case of tender and disabled spine following an attack of typhoid fever. I have seen two cases of this affection during the past two years, one of them at the expiration of eighteen months is scarcely well yet. The diagnostic points are, it comes on a short time after an attack of typhoid fever, is attended by great pain and tenderness of the spine, often of considerable vertical extent.

Infectious diseases.—Personally I have had no experience with disease of the spine following such infectious diseases as diphtheria, scarlet fever and measles. The apparent cause, the sudden onset, the acutely painful condition of the spine without deformity, the affection of several vertebrae and the rapid recovery, would distinguish this morbid condition from caries.

Page's disease.—It usually occurs late in life and is attended by a stiffening of the spine which is not very painful, and an exaggeration of the normal curves of the spinal column.

Hydatids of the spine.—It is probable that a diagnosis could be made only after the character of the cyst was ascertained.

Non-tuberculous traumatic inflammation of the spine.—It is probable that most of the inflammatory conditions of the bodies of the vertebrae, if they are not tuberculous at first, soon become so if the disease is not arrested.

Dr. S. A. Fisk said that his experience does not coincide with that of Dr. Eskridge. He has seen very little of tubercular bone disease in Colorado. He considers the idea that every bone disease is of tubercular origin to be a fallacy. It would be just as reasonable to say that every case of diarrhea in tubercular patients is of tubercular origin. He cited several cases which illustrated his standpoint. His treatment consists mainly in rest combined with fresh air and sunshine, a condition nowhere so ideally obtainable as in Colorado. He cited several cases of bone disease following typhoid fever, the affection having settled on the ribs, tibia, etc.

Dr. PACKARD discussed the mechanical treatment of Pott's disease. He said: It can safely be said that the results from medicinal treatment of Pott's disease in this country are generally superior to those obtained in any other country, and are largely due to the fact that the surgeon does not delegate to the instrument maker the adjustment and care of apparatus. Who would think of asking an instrument maker to adjust the splints in a case of fracture?

The results obtained vary according to the region of the spine involved. Caries in the cervical, lumbar and five lower dorsal give comparatively good results. It is the seven upper dorsal that give cause for anxiety.

The methods of mechanical treatment are limited to the jacket, the antero-posterior splint and the recumbent position. After having considered various methods of application, he concluded by saying: I want to emphasize the importance of continuing mechanical support for a long time after all the acute symptoms have disappeared, as the relief that follows efficient mechanical treatment is very great. Sometimes the friends of the patient are deceived by this and expect a rapid cure. There is also danger of the medical attendant becoming over-enthusiastic over the rapid improvement and consequently he may remove the support long before consolidation has taken place. Under these circumstances, a relapse is almost sure to follow.

PRACTICAL NOTES.

Ptosis Cured by Grafting the superior rectus on the tarsal cartilage, is reported by Motet of Angers; two cases.—*Progrès Méd.*, May 21.

The Endoascopic Sound is the name given by Remond and Noe to their instrument, presented at a late meeting of the Paris Académie de Médecine, which allows the insertion of the Crookes' tube into the cavities of the body, liquids, masses of muscle, etc., for diagraphy. Projections allowing for the known distortions complete the process and render the "views," mathematically correct.—*Bulletin*, May 10.

Skin Flaps retain their Vitality for weeks if kept in sterile ascites fluid as Ljunggren has demonstrated. He now reports a number of observations in which flaps six to nine days old were transplanted and healed into the tissues in the most perfect manner, with unmistakable evidences of practically unimpaired vitality.—*Deutsche Zeitschrift f. Chir.*, xlvii, 6.

Specula of Glass and Celluloid.—C. H. Stratz of Haag uses a speculum made of glass with an open tube space running through it to convey cauterizing substances to the portio and uterus without contact with the hand or vagina. The tissues can also be examined through the glass. He also recommends his celluloid speculum for hot water irrigations. Water of 40 to 50 degrees C. can be used without pain and with surprisingly favorable results in parametritis.—*Munich Med. Woch.*, May 10.

Infection of the Thread by the Fingers during the operation is the chief cause of stitch suppurations, O. Bloch believes. He recommends disinfecting catgut with phenicated water, which swells and softens it, hardening it again in alcohol. The needle and thread are held with forceps while being threaded and the latter not touched with the fingers more than can be avoided, and never any part that is to be left in the tissues.—*Revue de Chir.*, May 10.

Improved Technique of Electric Treatment for Vomiting in Pregnancy.—The patient eats at the séance, and then as the nausea appears, a single large electrode is applied, fitted to the neck, the median space insulated with rubber, each active end covering 20 square centimeters, over the vagus, with the negative electrode on the epigastric region, 150 square centimeters in size. Ten minutes arrested the nausea and six daily séances abolished it completely in one case reported.—*Semaine Méd.*, May 25.

Angiotripsy: Hemostasis without Clamps or Ligatures.—Tuffier reports twenty-three vaginal hysterectomies all successfully performed with the assistance of the new angiotribe. The ablation of the uterus proceeds as usual, but instead of applying clamps to the broad ligaments they are seized between the jaws of the angiotribe and crushed, the instrument then removed. The hemostasis is perfect (*Semaine Méd.*, May 25) Doyen's similar instrument exerts a crushing force of 400 to 1200 kilograms, and, he states, renders all operations in which it is used, much shorter and more certain.

Laparo-Hysterectomy for Carcinoma Uteri should be reserved for cases in the early stages, as otherwise even this serious operation proves merely palliative, like vaginal hysterectomy. Jacobs has only had two patients survive over two years out of seventy on whom he performed vaginal hysterectomy, and Bouilly's ultimate results in 127 are equally unfavorable. He considers it scarcely more effective than amputation of the cervix, as it is impossible to attain all the affected tissues. Out of eleven on whom he performed laparo-hysterectomy all recovered but one, who succumbed to pneumonia shortly afterward, but three already show symptoms of a recurrence in three to five months.—*Semaine Méd.*, May 14.

"Abaissement" Method of Inguinal Herniotomy.—Reille recommends this method for small and medium hernias as simple and reliable, after an experience of seventy-two cases. After the hernial sac is out of the way, the external oblique is slit at the external inguinal ring so as to expose the edge of the internal and transverse oblique. The spermatic cord is drawn down and the pillars of the external and transverse oblique are sutured, leaving only space for the cord, to the lower wall of the inguinal canal, and the slit in the external oblique is then sutured.—*Cbl. f. Chir.*, May 14.

In Operating Prolapsus, Saenger and Hegar both observe the following points: 1, very extensive denuded surfaces; 2, very exact, close stitches; 3, no catgut; Saenger uses fine silk and Hegar silver wire; 4, excision colli alta the sole operation on the uterus, as they consider ventrofixation entirely unnecessary, except with total prolapsus; 5, extreme care in details and time devoted to the operation, Saenger with all his dexterity, requiring three hours. The most scrupulous asepsis is a matter of course, and the patients are only anesthetized at the close, during the work on the peritoneum.—*Deutsche Med. Woch.*, May 19.

Osteomalacia.—Latzko has observed 120 cases and notes the diagnostic signs of sensitiveness to pressure of certain points of the skeleton, especially the pelvis and ribs, isolated paresia of the iliac psoas, contractions of the adducting muscles with impossibility to abduct the limbs, also exaggeration of the rotulian reflexes and absence of sensory disturbances. He has found phosphorus fully effective as castration in over 100 cases, and ascribes the failures of others with it to the fact that the doses were too small. He commences with one teaspoon a day of a solution of 6 centigrams of phosphorus in 100 grams cod-liver oil, increasing to eight or ten. The patient thus receives 4 to 6 milligrams of phosphorus a day. If there is no improvement in two or three months, the patient should be transferred to the hospital for better hygienic surroundings. If this also fails, then castration is indicated.—*Semaine Méd.*, May 14.

The Permanency of Cure after Ablation of Cancerous Tumors has acquired new interest since the publication of Schuchardt's case in which some of the probably affected glands, difficult of access during the laparotomy, were purposely left, to shorten the operation, although one of the neighboring glands examined by the microscope confirmed the diagnosis. The patient died some time after the operation and no cancerous glands were found at the necropsy. The question now is whether the laparotomy affected the cancer favorably as it does tuberculosis. A. Fraenkel thinks that permanent cures are more frequent than supposed, but Albert prefers the term "late relapses," observing that recurrences may develop as late as ten years afterward. Hochenegg states that out of 104 cancers of the rectum he has operated since 1887, forty-six are free from recurrences to date, one eleven years. A number of cases have been reported operated thirteen, eleven, eight and five years without recurrence. A recent discussion of the subject at Vienna concluded by urging operators to note whether the principle of "extensive regional ablation" is imperative in stomach, intestine, tongue and lip carcinoma, judged by the ultimate results, and what effect it has on remote metastases.

An Aseptic and Cosmetic Suture without a trace of the stitches is obtained by inserting the curved needle under the outer layer of the skin, first on one side and then on the other, and bringing it out at the extreme tip of the wound, fastening each end of the thread over a roll of gauze, after pulling it taut. This percutaneous suture ensures an absolute linear scar. To remove the thread pull hard on one end and cut it close to the skin. The rest is then easily pulled out at the other end, without carrying any germs from outside into the tissues. Each curved stitch should include a little larger space than the corresponding open space opposite.—*Münch. Med. Woch.*, May 24.

Permanent Drainage of Ascites is secured, by Prof. P. Fürbringer, by inserting the fenestrated end of a rubber tube fifty centimeters in length, inside a canula into the peritoneal cavity. The canula is then withdrawn and the tube fastened with a thread passing through the wall of the drain. While the fluid is draining out a small antiseptic dressing is applied around the point where it enters, and held with a circular bandage. When the fluid is evacuated the tube is closed with forceps where it emerges, the outer end rinsed with an antiseptic solution and then coiled and held in place with cords of tarlatan. Whenever the ascitic fluid has collected again, the forceps are removed, the tube uncoiled and drainage re-established.—*Semaine Méd.*, May 25.

Chloroform Anesthesia.—Groube has observed 40,000 cases of chloroform anesthesia, from 1851 to 1896, with three deaths. Examination of the urine before and after anesthesia showed that the chloroform does not affect the kidneys except in cases that have previously been chloroformed several times. He considers physiologic salt solution by far the best stimulant for the heart, denouncing alcohol and other carbohydrates on account of their depressing action. Asphyxia was threatened in 5 per cent.; relieved by a few manipulations for artificial respiration after removing the mucus accumulations. Vomiting was observed in 20 per cent.; ice was given in obstinate cases; bouillon and coffee only subdue the vomiting when they are very cold or very hot. He considers morphin useless in connection with chloroform anesthesia.—*Presse Méd.*, May 21.

Anchylostomiasis is frequent in the coal mines of Hungary. A physician at Brennberg reports 470 cases observed. He found santonin ineffectual, but ten grams of thymol a day resulted in the final expulsion of all traces of the parasite in four to six weeks. He usually administered extr. flic. mar. æth. in gelatin capsules, as much as fifteen grams in three hours, preceded by 0.4 gram calomel. Arsenic and iron for the pronounced anemia. The subjective disturbances were exhaustion, weakness below the knees, palpitations, dyspnea, buzzing in the ears, salivation, etc.—*Wien. klin. Woch.*, 1898, 19.

Ovarian Therapeutics.—Vigier has applied to ovarian substance the same process he has found so effective with thyroid tissue; after freeing the organ from all foreign substances, fibers, fat, etc., he mashes and mixes it with sodium bicarbonate and charcoal, which preserve it indefinitely without interfering with its therapeutic effect. Two to six capsules a day, each containing 0.20 gram have been found extremely effective in the troubles of the menopause.—*Gaz. Méd. de Liège*, May 19.

Arsenic Iodid in Scrofula has been found extremely effective by R. St. Philippe during the last three years in cases of chronic eczema, inflammation of the eyes, intestinal catarrh and other manifestations of "scrofula." In some cases the results were marvelous. Five to twenty drops a day of a 1 per cent. solution of arsenic iodid were administered, with no local treatment except rinsing with boiled water. The drug must be dissolved in cold water, and if symptoms of intolerance appear, suspended for a few days and resumed with smaller doses.—*Bull. de l'Acad. de Méd.*, April 19.

Prophylaxis of Movsble Kidney.—Keller considers pregnancy unfavorable to the development of this condition, but after delivery everything tends to produce it. He advises, as prophylactic measures, the wearing of a belt tighter above than below, remaining in bed at least three weeks, not sitting up before the seventeenth day, and resorting to the sound rather than allowing efforts during urination. A belt should be worn during pregnancy if the abdomen is very much stretched and at least six weeks after delivery. Pads are useless, but very thin women may be benefited by a bandage with spring plates. The effect of nephrorrhaphy is too often transient for it to be recommended. Nephrectomy is the last resource.—*Monatss. f. Geb. u. Gyn.*, 1898, January.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Foreign Postage 1.75
Single Copies 10 Cents.

In requesting change of address, give *old* as well as new location.
Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, JULY 9, 1898.

THE PROGRESS OF ARMY MEDICAL ORGANIZATION.

During the past month the organization for field service of the medical department of the various regiments aggregated in the camps of instruction at Chickamauga Park, Georgia; Tampa and Jeffersonville, Florida, and Camp Alger near Washington, D. C., has been progressing on lines indicated by the surgeon-general and the chief surgeon of the army in the field. The latter officer, Colonel CHARLES R. GREENLEAF, Assistant Surgeon-General U. S. Army, made an estimate of the medical and hospital personnel of an army corps for the guidance of chief surgeons in the organization of their field hospitals and hospital corps companies. In this estimate an army corps was assumed to consist of 24 regiments of infantry, 3 light batteries of artillery and 1 regiment of cavalry organized in 3 divisions of 3 brigades each, and that to man this command medically there should be, in accordance with existing laws and orders, a total of 89 medical officers, 83 hospital stewards, 29 acting hospital stewards and 817 privates of the hospital corps. To organize for field service, each regiment of infantry would have assigned for service with it 1 medical officer, 1 hospital steward and 1 mounted orderly; the battalion of 3 light batteries of artillery 1 medical officer, 3 acting hospital stewards and 1 mounted orderly, and the regiment of cavalry 2 medical officers, 1 hospital steward and 2 mounted orderlies. For administrative purposes at headquarters of corps, divisions and brigades: At corps headquarters 2 medical officers, 2 mounted orderlies and 1 hospital steward; at the headquarters of each division 1 medical officer, 1 hospital steward and 1 mounted orderly, and at the headquarters of each brigade 1

medical officer and 1 mounted orderly. For each of four ambulance companies, one to serve with each division and one to be held as a reserve, 6 medical officers, 7 hospital stewards, 3 acting hospital stewards and 104 privates of the hospital corps; and for each of four field hospitals, of 200 beds each, one to serve with each division and one to be held in reserve, 6 medical officers, 6 hospital stewards, 3 acting hospital stewards and 90 privates of the hospital corps. The assignments of the medical force of the army corps would thus be:

	Medical officers.	Hospital stewards.	Acting hosp. stewards.	Privates of hosp. corps.
On duty with regiments, batteries, etc.	27	25	3	27
On staff or administrative service	14	4	..	14
With ambulance companies	24	28	12	416
With field hospitals	24	24	12	360
Unassigned	2	2	..
Total	89	83	29	817

The difficulties encountered in effecting this organization have been due to opposition on the part of regimental officers, medical and line, to the breaking up of the regimental hospital which they have been accustomed to regard as an essential part of the regimental constitution. Chief surgeons were handicapped also by the dislike of volunteer soldiers to offer themselves for transfer into the hospital corps of the regular army. A third difficulty was found in the changes taking place in the composition of divisions as one or more regiments were sent from one command to another, from Chickamauga, for instance, to Tampa. When the medical department of a division is well organized and its members familiar with their work it is a simple matter to detach with one or two regiments an appropriate share of medical and hospital supplies and to adjust the duties of the remaining officers and men to the new conditions; but occurring frequently in the progress of organization such changes retard the work and increase materially the labors of the medical officers in charge.

RED TAPE.

Officers of the Volunteer Army are prone to consider as needlessly strict and formal many of the requirements of Army Regulations, particularly those relating to reports, returns and other so-called paper-work, and to make use of the term, red-tape, as embodying their opinion of all such requirements and as accounting for and excusing any ignorance of the subject on the part of those who, like themselves, have volunteered for the intensely practical work of grim-visaged war. But no business can be managed successfully without attending to the accounts. Even the small affairs of the family circle involve a certain amount of orders, memoranda and book-keeping to house, feed and clothe the members of the family and have the various bills settled at the end of the month. The company is the military family; and if its head, the company commander, fail to keep proper account of the pay due his men, if he fail to

inform himself of the regulation methods of providing them with food, clothing, arms, equipments, etc., or to turn this information to practical account, his men will suffer, for, as in military life, it is expected that every one should know his duty and do it; there is no provision by which the men of a command can be cared for when its own commander fails to do so.

Medical officers are in a great measure relieved from duties of this kind. The number who have to care for soldiers of the hospital corps is very small. They are the officers in charge of hospitals and of hospital corps companies. Regimental medical officers have with them on field service only a hospital steward and a mounted orderly, and these men are attached to some company of the regiment for rations and are borne on the rolls and returns of the field hospital or ambulance company for muster, pay and clothing. Regimental medical officers have been relieved from cares of this kind that they may be able to devote all their attention to the keeping of accurate medical records of their regiments. In every case of serious sickness, death or discharge for disability every important detail should be entered on the register of patients. Indeed the case of every man who is treated on account of accident or sickness should be entered on this register, which is practically a retained copy of the regulation monthly report of sick and wounded. The calls made by chief surgeons for care in filling out the columns of this report are regarded as red-tape by some medical officers who consider that their duty is the practical one of caring for sick and wounded men, and that if this is done conscientiously it matters little whether or not any written record of the cases be made. They overlook the fact that this monthly report of sick and wounded when filed in the War Department will constitute the only medical evidence on which hereafter claims for pension will be decided. In this lies its importance. The medical records of the early months of the Civil War were very defective and great injustice both to individuals and to the Government was undoubtedly caused thereby. The Medical Department at the present time should profit by the experience of the past and should put as much energy into its methods as will ensure the rendition of accurate reports from every volunteer command.

THE HEALTH OF SANTIAGO DE CUBA.

We learn that during the past ten years there have been two epidemic visitations of yellow fever in Santiago and its neighborhood, with cases scattered in the intervening years, so that the infection of the fever must be considered to be there and ready at any time, under favorable conditions, to cause an outbreak among our unacclimated men when they leave the mountains and enter the city. In November, 1890, after a period of freedom from fever, the disease was introduced into Santiago and its vicinity by workmen

from Spain who had been ashore for some days at Porto Rico while *en route* to Cuba. Yellow fever was then prevailing at Porto Rico and some of the Spanish emigrants became infected. These settled in Santiago and introduced yellow fever among the people employed at the Juragua Iron Works. The disease prevailed at these works for twelve months, attaining its maximum in June, 1891, during which month there were 57 cases, of which 21 were fatal, among the 1300 people in the employ of the Iron Company. During the twelve months the epidemic gave a sum of about 265 cases, of which 100 were fatal. A few cases occurred in the winter of 1892-93 and again in the winter months of 1894; but in July, 1895, something like an epidemic was again lighted up, lasting until November and giving 107 cases, of which 47 were fatal. The disease prevailed at these periods among the population of Santiago. Since then only sporadic cases have occurred.

THE SKIN AFFECTIONS OF TYPHOID FEVER.

In a disease so prevalent and wide-spread as typhoid, necessarily lesions of any and all systems occur, some of which may be regarded as accidental and casual, while others from the comparative frequency with which they exist must be looked upon as in the nature of complications. Indeed, a third class may be added, that of intercurrent affections, those diseases which might with great probability never have occurred had not the resisting power of the economy become so impaired by the ravages of the disease that ready entrance is allowed to the specific organisms of other affections, which in a healthy state of the body could not have obtained a foothold. Of these germs streptococci, staphylococci and pneumococci, play a leading part; they also contribute largely to what might be called the complications proper, while late reports show that the typhoid bacillus itself is amply able to produce some of the most important complications of the disease, as in the cases of OHL-MACHER, in which he isolated this germ in two cases of meningitis ("Clinical and Pathologic Features of Two Cases of Typhoid Meningitis," by O. P. OHL-MACHER. The *Cleveland Medical Gazette*, May, 1897). As regards the dual role of the pus organisms, especially the streptococci, they now produce an attack of erysipelas, an intercurrent affection; now occur in suppurative parotitis and other abscess formations, complications. It is sometimes difficult to say whether pneumonia acts as an intercurrent disease or as a complication, but the endo- and pericarditis occurring in typhoid and pneumo-typhoid so-called, are complications.

The skin, from its very office of protector and from its exposed situation, is especially liable to disease, and the lowered vitality of the body in typhoid does not tend to diminish this danger; the integrity of the appendages of the skin becomes still more jeopardized

because of correspondingly greater impairment of nutrition. To the student of typhoid, the most important skin lesion, both on account of its frequency and its diagnostic value, is the eruption of the rose-colored, lenticular spots; papular elevations, usually situated upon the abdomen, though they may be found on any part of the trunk and even on the face and extremities, occurring as a rule in suddenly appearing crops which, lasting a few days, gradually disappear, leaving brownish stains; occasionally they become capped by a small vesicle, but even in the malignant cases rarely if ever become pustular; indeed, in the malignant cases they are more likely to be the subjects of hemorrhage, forming the so-called petechiæ. They rarely exceed four millimeters in size and disappear readily on pressure, only quickly to reappear when the pressure is removed.

In cases which perspire considerably, especially those cases in which the coal-tar antipyretics have been given and even sometimes after the bath, miliaria vesicles or sudamina are often present, particularly on the chest and abdomen. With the establishment of convalescence these disappear, and where they have been abundant, a branny desquamation not unlike that of measles often follows.

Any one who has seen considerable of hospital practice has doubtless noted the frequency with which steel gray or more often pale blue spots are seen beneath the skin of the abdomen, chest, and particularly the thighs. These peliomata, as they are called, are not confined to typhoid, are usually somewhat irregular in outline, are larger than the rose spots, do not disappear on pressure, often cause the victim to irritate them by scratching, and are undoubtedly due to the presence of pediculi.

During the early stages of the disease, and especially if any of the coal-tars or quinin have been administered, an erythematous rash may appear, first on the chest as a rule, usually extending from there all over the body with the exception of the hands and face. This rash occurs with considerable frequency, rather more so than either urticaria or herpes, neither of which are by any means uncommon. GILMAN THOMPSON, in his report of "Unusual Complications of Enteric Fever" ("Medical and Surgical Report of the Presbyterian Hospital in the City of New York," 1898), speaks of two skin lesions, purpura hemorrhagica and papular eczema. He reports a case of the former at some length after giving a typical history of typhoid infection. "On examination he appeared neither anemic nor emaciated. The temperature was 104; pulse, 90; respiration, normal. The Widal reaction was obtained. The urine was normal. The skin was somewhat hyperemic, and a number of typical enteric spots were present upon the abdomen, lower chest and arms. The spleen was barely palpable, and the liver appeared an inch below the costal margin. No other visceral abnormalities were discoverable.

There was moderate alcoholic tremor. Two days after admission severe epistaxis returned, which the house physician was only partially able to control by plugging and the use of styptics. At this time a number of small hemorrhagic spots appeared, scattered over the back and upon the left forearm. The dejecta were slightly streaked with blood. During the next three days the patient became excessively weak from loss of blood and during the period from the ninth to the twentieth day of the disease, he showed no improvement. The temperature rose to 105.6 and remained steadily high (104.5). The urine became hemorrhagic, showing red blood cells, hemoglobin, leucocytes, hyaline casts and albumin. 35 per cent. by volume. Well-marked Ehrlich reaction was present. Subconjunctival hemorrhage took place in the left eye, and the ecchymoses became abundant over the chest, abdomen and extremities. They were also observed on the buccal mucous membrane. . . . The tongue became dry and fissured. there was bleeding from the gums and the breath was foul. . . . During the fourth week of the disease there was no increase in the purpuric spots, many of which began to fade, but the other symptoms continued with occasional attacks of epistaxis. Slight hemorrhage also occurred from the left ear. . . . During the fifth and sixth weeks slight improvement gradually supervened, the urine became less hemorrhagic, epistaxis ceased, and on the forty-second day of the disease, the morning temperature reached the normal for the first time."

Of other lesions of the skin, not eruptive in character, one of the most common is edema. This may result from a variety of causes, as thrombosis of a vein (especially the femoral), as a sequence of nephritis, but most commonly in the lower extremities, due to the cachexia and emaciation produced by the disease. In the latter instance the edema is most apt to manifest itself when the patient begins to walk around, and indeed almost every case of severe typhoid is more or less subject during convalescence to this annoyance. Even the laity are familiar with the frequency with which alopecia occurs in this disease, and they are likewise imbued with the hope that their hair will "grow in curly." Occasionally permanent baldness results, but the instances are very rare. Of the other appendages of the skin, the nails also suffer from lack of nutrition, and one can often make the diagnosis that a patient has been suffering from some prolonged illness, presumably typhoid, by transverse ridges appearing on the nails several weeks after convalescence has become established.

The skin phenomena occurring as a result of nervous influence brings us toward the end of our subject. The vaso-motor phenomenon known as the *luche cérébrale*, produced by running the nail rapidly over the skin, when a red line with white boundaries is formed, is not peculiar to typhoid but may be present

in any fever. Exposure of the skin of any part of the body which has been or is usually covered, often causes in nervous subjects a pinkish injection of the skin of the exposed parts. This is commonly seen when the attending physician draws down the bed clothes in his examination for spots or enlarged spleen. As a sequel of typhoid, a lesion has often been observed, and in males as well as females, of the *linear atrophica*, usually known in obstetric practice as the "silver lines of pregnancy." These whitish streaks, occurring for the most part on the abdomen and hips, are undoubtedly due to neuritis.

Other diseases, intercurrent in character, may occur and produce skin eruptions of their own. Erysipelas may coexist with typhoid or be induced by the lowered vitality produced by the latter, and gangrene may be superinduced as the result of pressure. This gangrene is usually of the moist variety, and may manifest itself in one or both legs, or over the lower part of the spine (as a bed sore), or in the cheek as a gangrenous stomatitis or noma. Indeed, noma follows typhoid more frequently than any other disease, unless it be measles.

PREMATURE OLD AGE. HOW TO AVOID IT.

A long life is variously valued by different individuals, but the great majority will without question accept it as a desirable acquisition. The ones who would theoretically disclaim any desire for length of days would in many cases exhibit the same objections to an early death or even one at any time, as those who honestly admit their preference for life even at the expense of the disagreeable possibilities of old age. The instinct of self-preservation, the clinging to life, is a safeguard of the race and it is to be hoped at least that it may never be a less prominent characteristic of mankind than it is at the present time. Old age is inconvenient, in some respects unattractive, and it is certainly a matter of expense to care for those who are past the productive period of their lives and who have not the excuse for their existence of the equally unproductive infant, that their term of usefulness is still to come. Nevertheless none of us who have a properly constituted disposition would wish matters otherwise than they are or care to lose prematurely, even for a moment, those who have passed the meridian and are now on the downward grade of life, however unproductive or burdensome they may be. There is a credit to their account in our social bank for past services which we can not ignore.

While old age is honorable and its infirmities are to be respected, it is not desirable nor, in a medical point of view, the proper thing for them to appear before their time. Premature old age means that the individuals or their ancestors, it may be back to the third or fourth generation, have sinned against their physical welfare and are reaping the reward. While

the most of us are probably more or less handicapped by heredity, it is well to know how to avoid the evil effects of a bad inheritance and to so train up the mature man in the way he should go that when he is old he will still have as few of the drawbacks of senility as is possible, and above all that he may not acquire these out of due time. This avoidance of premature old age forms the subject of a very readable and instructive article by Dr. HERMANN WEBER in a new publication, the *Zeitschrift für diätetische und physikalische Therapie*, the first issue of which has just appeared, an article which would be well worthy a wider circulation than it is likely to have in a special German medical magazine. It would be impossible to abstract it here fully, but one or two of the points made by the author can be mentioned. It is well known that the chief cause of senile failure is to be sought in the circulation; the nutrition of the brain and nervous system suffer from the incapacity of the heart and the rigidity and narrowing of the vessels through atheromatous and other allied conditions. If the finer vessels of the brain lose to any extent their facility of functioning, their elasticity, then the nerve cells suffer, both those of the cortex and the basal ganglia. To a lesser extent this same is true as regards the minute vessels of the heart itself and of the stomach in their action in bringing on the changes characteristic of senility; the disturbances of the functions of the heart itself are the causes of secondary lesions elsewhere, and the importance of the normal functions of the digestive and the excretory organs needs no extended elucidation. The causes of the early appearance of these vascular changes themselves are the important element of the question, and Dr. WEBER's views on this point are well worthy of notice. According to him, the chief producers of these vascular degenerations are over-nutrition, inactivity both of mind and body, too much sleep, and not infrequently with these we find alcoholic excess and immoderate use of tobacco. A too engrossing and monotonous occupation and emotional depression of any kind may also have its share. Over-feeding and inactivity are generally recognized causes of physical degeneracy, but it has not been so common to attribute to over-sleeping the importance here given it. His view that for most people over the age of fifty, six or seven hours of sleep is an ample allowance may not be in accord with the preconceptions of many, but it has a certain reasonableness. The fact that in all probability there is a more sluggish cerebral circulation and more opportunity for stasis and obstruction is in its favor. Wakefulness has been reckoned as an indication of senility, but according to this theory it is a conservative symptom and encouraging rather than otherwise. As Dr. WEBER says, it is difficult to lay down rules in a matter in which there are so many and so wide individual differences, and there are many con-

ditions in which abundant sleep is beneficial; yet, for the majority of healthy and especially of elderly individuals, temperance in sleep is as important as that in other restoratives and sedatives.

Another important matter, but one that has less apparent novelty, is the need of mental and bodily activity for warding off the symptoms of premature senility. The instances of extreme longevity are, it is true, to a large extent those who have led a simple quiet life, apparently without startling vicissitudes or excessive bodily or mental exertion. But with these we have abundant examples of active intellectual work carried on in extreme old age, and on the other hand we have every day instances of rapid failure after the cessation of regular accustomed employment. While the bodily powers lessen to some extent with age and require some modification of the activities, any sudden interruption or diminution of them may be disastrous. The recommendation that every man should have some hobby or side issue of interest is not a bad one, and may maintain the zest of life when the regular occupations are laid aside.

A happy and hopeful disposition, it goes without saying, is a wonderful aid in warding off and tempering the discomforts of old age. The use of alcohol in moderation is commonly thought to be beneficial in the aged, and St. PAUL's recommendation of a little wine for the "often infirmities" is frequently repeated by the laity and endorsed by the physician. Dr. WEBER does not endorse this view; wine, in his opinion, is not *die Milch der Greise*, and is not effective in staying off the weaknesses and defects of advancing years.

With all our much discussed degeneracy of modern times, man is now a longer-lived animal than were his forefathers, though the evidence of this is perhaps more apparent in actuaries' tables than in striking individual cases. What we need now, as at all times, is more popular enlightenment in regard to the important hygienic question of how to meet the inevitable downward stage of life, to mitigate its necessary disadvantages and to avoid those that can be spared us. We ought all to know how to grow old becomingly and comfortably; with this knowledge, practically applied, the extension of life will be in every way more desirable and enduring.

DESPONDENT OUTLOOK FOR SPAIN AND OTHER LATIN PEOPLES OF EUROPE.

Dr. GUIDO BACCELLI of Rome, who was president of the Eleventh International Medical Congress, and who has been called the Italian Virchow, has made known certain pessimistic views of the Spanish trouble. He thinks Americans are more to be dreaded by the Latin nations than the Chinese. The yellow races, he thinks, no longer menace Europe, but there is actual menace from the United States, "where the expanding, absorbing Anglo-Saxon or cosmopol-

itan energy must grow and spread and ultimately overwhelm that part of European civilization which it does not renew. War with Spain is the beginning. Afterward it will be a mere question of the "survival of the fittest." In other words the humanitarian instincts and voice of the northern races must be listened to and taken into the account by the more heartless and tyrannous people of the south of Europe,—and in the name of sweet charity is it not about time that a new leaf should be turned? Americans are not anxious for territorial aggrandizement, but it is due from us to those countries that may come to us by conquest, that their kind of government shall cease to be of the Spanish variety. And further, when the Latin peoples are entirely ready for arbitration instead of war as the standard method of settling international troubles, they will find in the United States a hearty friend of peaceful measures. We do not love war, the destructive arts have been cultivated far less than the constructive ones, so that some of our good friends across the water have actually fallen into the belief that any old nation might bite its thumb at us with impunity. As ARTEMUS WARD might have expressed it, "Arbitration is the *best holt* of the alleged deodant Latin peoples of Europe," and the same may be said on behalf of the peoples that are coming strongly to the front.

But there must first be an end of Spanish arrogance, bluster, insufferable assumption, sanitary crimes and unspeakable cruelties. Pending the general adoption of the wholesome principle of arbitration as a means of settlement of international difficulties, we rely on the persuasive cannon of DEWEY, SCHLEY, MILES and SHAFER to teach the Spaniard his unwelcome lesson.

CORRESPONDENCE.

WAR CORRESPONDENCE.

BY LIEUT.-COL. NICHOLAS SENN, U.S. VOLS.,

CHIEF OF OPERATING STAFF WITH TROOPS IN THE FIELD.

War always has been and always will be a cruel thing. The very object of war is to kill, disable, maim and starve until the result of the contest shall decide the issue by demonstrating the superiority of one army over the other in number, courage or skill of warfare. "The battle is the Lord's," but victory is not always on the side of justice. The Lord teaches, rules and benefits the children of men now, as during the time of the prophets, as often by defeat as victory. The God of battles has ways and means often impossible to comprehend, but they always lead to results beneficial to mankind. The terrors and sufferings of war are the prices paid for defeat as well as victory. The wonderful improvements made in weapons and projectiles during the last quarter of a century have made modern warfare more destructive if not less cruel. It is difficult to foretell the relative number of dead and wounded in the engagements of the future. Reliable information on the subject must come from actual observation on a large scale on the battlefield and not from the results of experiments on the lower animals and the cadaver. Warfare has become a science and an art,

and victory will depend as much on the skill and foresight in strategy of the commanding officers as the endurance and valor of the troops. The long range rifles and the better marksmanship of the average soldier will increase the distance between the fighting lines and give the commanding officers better opportunities for the exercise of their skill in maneuvering the troops. In every respect war will and must assume more scientific aspects for the display of skill. What the improvements will be can only be determined by experience on a large scale. The rapid mobilization of troops, supply of ammunition along the line of battle, flank movements, the quick digging of shallow entrenchments for the protection of the soldiers in line of battle, are some of the important subjects which are engaging the minds of our wide awake military officers and which await a satisfactory solution by as yet an unknown second Napoleon. Let us hope that this important person is now in existence, an American citizen and now engaged in the present war with Spain.

HOSPITAL CORPS.

The humane side of the present methods of warfare is best shown by the organization of an efficient hospital and ambulance corps. The sick and wounded of the great war of the rebellion suffered indescribable pain and agony owing to inadequate provisions for transportation, first aid and nursing by men detailed for this special purpose. Our sick and wounded

Private, hospital corps U.S. Army, field equipment (front view).

can look forward more hopefully for more prompt and efficient treatment. The Government, through the Surgeon-General and Secretary of War, is making ample preparations for the prompt and efficient treatment of those requiring medical or surgical aid. The prevention of disease by the employment of improved hygienic and sanitary measures will do much in minimizing the number of ignominious deaths in the field and general hospitals and in maintaining the full fighting force. The need of a well organized and well equipped hospital corps became apparent during our late war, but it was many years after the Union was restored before the necessary legislation was effected which brought it into existence. The Hospital Corps in the United States Army was created by an act of Congress approved March 1, 1887.

The law under which the Hospital Corps was established and as revised by March 16, 1895, and March 16, 1896, reads as follows:

(The Military Laws of the United States, 1897.)

"673. That the Hospital Corps of the United States Army shall consist of hospital stewards, acting hospital stewards and privates; and all necessary hospital services in garrison, camp

or field (including ambulance service) shall be performed by the members thereof, who shall be regularly enlisted in the military service. Said Corps shall be permanently attached to the Medical Department, and shall not be included in the effective strength of the Army nor counted as a part of the enlisted force provided by law.

"674. That the Secretary of War is empowered to appoint as many hospital stewards as, in his judgment, the service may require; but not more than one hospital steward shall be stationed at any port or place without special authority of the Secretary of War. That there shall be no appointments of hospital stewards until the number of hospital stewards shall be reduced below one hundred, and thereafter the number of such officers shall not exceed one hundred.

"675. That the pay of the hospital stewards shall be forty-five dollars per month, with the increase on account of length of service as is now, or may hereafter be allowed, by length of service, as is now or may hereafter be allowed by law, to other enlisted men. They shall have rank with ordnance sergeants and be entitled to all the allowances appertaining to that grade.

"676. That no person shall be appointed a hospital steward unless he shall have passed a satisfactory examination before a board of one or more medical officers as to his qualification for the position, and demonstrated his fitness therefor by service of not less than twelve months as acting hospital steward; and no person shall be designated for such examination except by written authority of the Surgeon-General.

Litter drill.

"677. That the Secretary of War is empowered to enlist or cause to be enlisted, as many privates of the Hospital Corps as the service may require, and to limit or fix the number, and make such regulations for their government as may be necessary; and any enlisted man in the army shall be eligible for transfer to the Hospital Corps as a private. They shall perform duty as wardmasters, cooks, nurses, and attendants in hospital, and as stretcher-bearers, litter-bearers and ambulance attendants in the field, and such other duties as may by proper authority be required of them.

"678. That the pay of privates of the Hospital Corps shall be eighteen dollars per month, with the increase on account of length of service as is now or may be hereafter allowed by law to other enlisted men; they shall be entitled to the same allowances as a corporal of the arm of service with which on duty.

"679. That privates of the Hospital Corps may be detailed as acting hospital stewards by the Secretary of War upon the recommendation of the Surgeon-General whenever the necessities of the service require it; and while so detailed their pay shall be twenty-five dollars per month, with increase as above stated. Acting hospital stewards, when educated in the duties of the position, may be eligible for examination for appointment as hospital stewards as above provided."

Since the original law providing for a hospital corps was passed many new features have been added which have made this branch of the military service more efficient.

The pay of members of the Hospital Corps is according to grade, as follows per month: Hospital steward, \$45; acting hospital steward, \$25; private, \$18.

To the rates of pay enumerated above, 20 per cent. is added in time of war.

During the present war the commander of an army corps, or of a division, or of a brigade acting independently of a corps, has full control of enlistments for the Hospital Corps within his command, and of the detail of acting hospital stewards and the appointment of hospital stewards. The Hospital Corps force of the present war is made up three per cent. of the privates obtained by special enlistment or transfer from the line, that is, a regiment of 1000 men is entitled to 30 men for the Hospital Corps. The allowance for horses, wheel transportation and tentage is ample, as will be seen from the following order recently issued by the War Department:

Litter drill.

GENERAL ORDERS.
No. 76.

HEADQUARTERS OF THE ARMY,
ADJUTANT GENERAL'S OFFICE,
WASHINGTON, June 22, 1898.

1.—By direction of the Secretary of War, the following allowance of horses for mounts, wheel transportation, tentage, etc., for the Medical Department of the Army in the field is authorized:

HORSES FOR MOUNTS.

	Hospital stewards.	Acting hospital stewards.	Privates.
To each regiment of infantry	1	1	1
To each artillery battalion (3 light batteries)	1	3	1
To each cavalry regiment	1	2	2
To each corps headquarters	1	1	1
To each brigade headquarters	1	1	1
To each division ambulance company	7	3	12
To each corps reserve ambulance company	7	3	12
To each division field hospital	2	2	6
To each corps reserve hospital	2	2	6

Wheel transportation.—One ambulance to 400 men of the effective force. One 4-horse wagon to 600 men of the effective force. One 4-horse wagon to each brigade.

Tentage.—For each ambulance company: 17 common tents for privates; 2 common tents for noncommissioned officers. For each division field hospital: 15 common tents for privates; 2 common tents for noncommissioned officers; 1 common tent for supplies. Hospital tents on a basis of 6 patients (beds) to each tent. Hand litters, with slings, to be furnished by the Quartermaster's Department: 1 for each company; 2 for each ambulance.

Requisitions for the necessary articles of camp and garrison equipage, tools, etc., will be based on the official allowances for companies of infantry.

Requisitions for the before mentioned supplies will be sent in separately for divisions, with statement whether or not the division organization is complete.

Horses and wheel transportation will be furnished by the Quartermaster's Department, and horse equipments by the Ordnance Department.

II.—Commanding Generals of Army Corps are directed to detail, upon the application of Chief Surgeons of Corps, two officers not above the grade of first lieutenant for duty as Acting Assistant Quartermasters with the medical service of each division.

BY COMMAND OF MAJOR GENERAL MILES:

H. C. CORBIN,
Adjutant General.

As usual, many difficulties have presented themselves in the way of securing the necessary material both in quantity and quality, for the Hospital Corps during the present campaign. The commanding officers are always averse to lose the most desirable men of the line. I have reason to believe that at the present time the importance of a good Hospital Corps is appre-

Ambulance in use.

ciated more than ever by the commanding officers. The field officers have co-operated with the corps surgeons in the selection of the best men for this special service. The work of organization has progressed slowly, but on the whole in a satisfactory manner. The enormous demand for equipments and the sudden mobilization of troops have contributed much in retarding the organization and instruction of the Hospital Corps. The designation of the Corps as a Hospital Corps does not convey the proper meaning of the manifold purposes for which the men are enlisted and transferred, and has been the means of misleading many a patriotic doctor and medical student now engaged in this branch of military service. Many

Travois.

complaints are heard because instead of doing hospital duty proper the men are made to cook, drive ambulances, chop wood, dig sinks and haul water. There are today too many doctors and medical students in the Hospital Corps. The duties of the Hospital Corps are manifold, and in their proper discharge requires more skilled artisans than medical men. A good Hospital Corps should consist largely of young, bright, intelligent, robust men skilled as carpenters, cooks, blacksmiths, stenographers, photographers, ambulance drivers, tailors, shoemakers and other trades. Doctors and medical students should be in the minority, and ought not to exceed twenty-five per cent. of the non-combatant force. If the legitimate function of

the Hospital Corps were better understood there would be fewer applications for this service on the part of professional men. The general impression prevails that the duties of the members of the Hospital Corps are less onerous than those of the private soldier of the line. It is difficult to conceive how such an idea could have originated. It is also understood that the non-combatant soldier is exposed to less risk of life than his comrade of the line, when the fact is apparent that in addition to the ordinary dangers incident to warfare, he is more exposed to the greatest source of danger—disease. The nursing in the field hospital is done exclusively by the Hospital Corps men, and involves much loss of sleep and constant care and attention. The transportation of sick and wounded is a task requiring good judgment, promptitude and care. A combination of firmness and gentleness, thoughtfulness of action and a determination to perform duty regardless of rest and comfort, is an essential element of success in the work of every Hospital Corps man. The climatic influence, the prevalence of tropical diseases will tax to the utmost the resources of the Hospital Corps during the present war with Spain. That the work will be well and cheerfully done I have no doubt, judging from my observations during the last two months.

The American people expect that the sick and wounded of this war shall receive the best possible attention, and in this they will not be disappointed. The Government, although sometimes necessarily tardy, is willing and anxious to do all in its power to alleviate the horrors of this war, and in this humane intention it will receive the hearty co-operation of the Hospital Corps. The writer has been permanently detached from the Sixth Army Corps now at Chickamauga by a recent order, and is now on his way to Santiago de Cuba on special duty. He goes to the front as Chief of the Operating Staff with the troops in the field. For the purpose of informing my many friends among your readers what I am expected to do, I append a copy of the letter assigning me to my new field of labor.

HEADQUARTERS OF THE ARMY.

WASHINGTON, D. C., June 29, 1898.

Lieutenant-Colonel NICHOLAS SENN, U. S. V., Chief of the Operating Staff.

Sir:—In assigning you as Chief of the Operating Staff, the Major-General Commanding the Army directs me to say that, at the several points to which you may be assigned to duty, you will confer with the Chief Surgeon of the Corps engaged as to the means by which you may consult with and advise the medical officers serving with that army regarding the clinical features of their professional work; that you will recommend such methods, either by lectures or operative demonstration, as may in your judgment be best suited to accomplishing the purpose in hand; that you will take the necessary steps for collecting data upon which the clinical and pathologic records of the field and hospital service may be classified, and from which the future medical and surgical history of this war may be prepared. Your present assignment will be for duty with the Fifth Army Corps, now operating before Santiago de Cuba, and at such future time as the General Commanding may decide, you will be transferred to other points where active military operations are progressing.

Very respectfully,

COL. CHAS. R. GREENLEAF,

Aest. Surg.-Genl. U. S. A., Chief Surgeon, Army in the Field.

I hope I will reach Santiago before surrender and enter it with our victorious troops. My address for the present will be

Fifth Army Corps, Santiago, Cuba.

My next communication will be from the seat of war.

Cerebro-Spinal Meningitis--A Correction.

ELMDALE, KANS., June 28, 1898.

To the Editor:—An oversight in reading the proof of "Cerebro-Spinal Meningitis" allowed sixth line from bottom, first column, page 1499, Vol. xxx, to read "50 per cent." instead of "20 per cent."

Very respectfully,

J. F. SHELLEY, M.D.

The Permanent Secretary Explains.

PHILADELPHIA, June 27, 1898.

My Dear Dr. Hamilton:—I have just read your editorial, and feel that it is due to myself to say that at the close of the session on Friday, I was ready to turn over to Mr. Whitford the minutes in full, but was compelled to wait the return of the papers containing the resolutions, etc., which were referred to the Business Committee, and reported upon by them on Thursday, but which were retained by the Secretary of that Committee that he might put them in order. The enclosed copy of a letter from him received by me on Friday morning will explain why they were not ready then for incorporation in the minutes:

Brown-Palace Hotel,

DENVER, COLO., June 10, 1898.

My Dear Dr. Atkinson:—It has been absolutely impossible for me to write up the records of yesterday in my Executive Committee book, and as I am off today I am taking them all with me to New York. They are all safe and will be sent to you when I return, but perhaps not for two weeks or so.

If there was anything else referred to the Committee yesterday or today kindly let me have it as soon as possible.

I remain, yours truly,

[Signed] L. DUNCAN BULKLEY,
Sec'y Executive Com. A. M. A.

You see that I am powerless, as it was my duty to give to this Committee all the matters referred to it. Nor did I think for one moment that they would not be at once handed to me when the report was made and acted upon by the Association. May I ask the publication of this reply as prominently as your editorial?

Yours very truly,

W. B. ATKINSON,

Permanent Secretary.

[When the reports on the resolutions were read by Dr. Bulkley, they were then the property of the Association, and he had no more right to carry them away than any other member. There is no "Executive Committee."—Ed.]

Dr. Eichberg.

CINCINNATI, June 29, 1898.

To the Editor:—Please correct statement of your Cincinnati correspondent, in last issue, that "Dr. Jos. Eichberg has resigned from Miami Medical College." He has resigned the office of Secretary, but retains his position of Professor of Practice. Dr. Olive P. Holt has been made Secretary of the College.

Respectfully,

WM. H. TAYLOR, Treas'r M. M. C.

ASSOCIATION NEWS.

American Medical Association.

Official Minutes of the General Sessions of the Forty-ninth Annual Meeting, held in Denver, Colo., June 7, 8, 9 and 10, 1898.

(First Gen. Session, continued from p. 1533, Vol. XXX.)

Dr. Bulkley, Secretary of the Business Committee, read a report of that Committee relative to prize essays, the publication of the Association program and the general sessions. The following is the report on the general sessions and Section meetings:

Resolved, That the Sections be directed to hold no meetings during the hours set for the transaction of executive business in the general sessions, and that the general sessions take place at 11 A.M., instead of 10 A.M.

Dr. Dudley S. Reynolds of Louisville—I move that the report of the Business Committee be adopted. Seconded.

Dr. Wm. H. Humiston of Cleveland—I object to adopting the resolution with reference to deferring the meeting of the General Session until 11 o'clock. It will encroach upon the work of the Sections. If the General Session is postponed until 11 o'clock, and then continue until 2 o'clock, which is likely to be the case, we will have practically no time for dinner, and it will interfere materially with the work of the various sections.

Dr. J. B. Hamilton of Chicago—I would respectfully dissent

from that part of the report which states that the program has not been published as a whole. That statement is incorrect, because each Section of the program has been published as received. It is not possible to publish them as a whole, because up to the last minute corrections are made which appear in the finished program. As these corrections were received not more than ten days before this meeting, how is it possible to print the program as a whole, when we only received the final program from the bindery last Friday?

Dr. H. M. McConnell of Pennsylvania.—I move, sir, that we strike out the word *adopt* and insert in its place the word *receive*. Seconded.

Dr. Daniel R. Brower of Chicago.—I wish to state that if we meet in general session at 11 o'clock, it will give the various Sections two hour's work, namely, from 9 until 11. Furthermore the best material of this convention will be in the Sections. (Applause.)

Dr. Leartus Connor of Detroit.—The remarks of the last gentleman meet with my approval. It would meet with my approval if these general meetings were never called until 12 o'clock and be closed at 1. (Applause.) I submit to the gentlemen present whether the presentation of matters this morning is worth our while to travel a thousand miles to listen to. The affairs of this Association should be so conducted that it will pay us to attend the meetings. We are here for business, not to hear about the Rush Monument Fund and a lot of other things of which most of us knew before. During the reading of these reports we simply go to sleep. Some of the members were sleeping around me this morning. We are not here to be put to sleep by bad air, or to be shut up in a sweat-box over matters in which we have no earthly interest. This is the work of committees and for which we appoint them. The benefit of these meetings is to be derived from attending and participating in the work of the Sections. It is only right that we should all attend these general meetings, and take an active part in the transaction of business, and if we are prompt the business can be transacted in a short time, and it will not burden any of us to do it. Those who have the arrangement of the meeting in charge should see to it hereafter that the business of the Association shall be transacted in one hour each day if possible. That is all the time we will need if we are prompt in our work. Let us have more time for Section work where we have the brains of the Association, and where the enjoyment comes and profit follows. In this way we will make the JOURNAL better and our meetings will be meetings of pleasure and of satisfaction to us all. Let us encourage all of our friends to come together and join with us to work in the interest of medical science and not listen to a lot of rot. (Loud applause.)

The motion to receive was put and carried.

On motion the Association adjourned until Wednesday, 11 A.M.

JUNE 8—SECOND GENERAL SESSION.

The Association met at 11 A.M., and was called to order by the Second Vice-President, Dr. J. A. Thompson of Indianapolis.

The minutes of the previous General Session were read by the Permanent Secretary and approved.

Dr. Graham of Denver made some announcements on behalf of the local Committee of Arrangements.

The Fourth Vice-President, Dr. T. J. Happel of Tennessee, now took the Chair.

Dr. Bulkeley stated that the Business Committee was unable to present a report upon the President's Address or upon the Rush Monument Committee, but that such report would be presented tomorrow.

Regarding the resolution in reference to Associations of the United States, the Business Committee simply reported progress and asked that the matter be referred to the Committee for another year.

On motion, the wish of the Committee was granted.

The Business Committee recommends for adoption the following resolution, which was sent to them with the endorsement of over twenty members of the Association in order to save time on the floor. The resolution is not directed to the Committee, otherwise it would be naturally referred to the Committee.

Resolved, That the Sections be directed to hold no meetings during the hours set for the transaction of executive business in General Sessions, and that the General Sessions take place at 11 o'clock instead of 10 after the first day.

Dr. Bulkeley moved that this resolution be adopted. Seconded.

Dr. H. M. McConnell of Pennsylvania.—I think the General Session of the first day should commence at 10 o'clock. That is the day when we have so much to do, and I would therefore move that the General Session on the first day be begun at 10 o'clock, and thereafter at 11. I offer this as an amendment. Seconded.

Dr. Alonzo Garcelon of Lewiston, Maine—I do not rise, Mr. President, to speak to the amendment particularly. I have no objection to that. I wish to say that the business of the General Session can not be properly attended to if we meet at 11 o'clock. There is a vast amount of very important business to be done at every General Session. I have been a member of the Association for a great many years, and I know very well the difficulty there is in getting through with our business, even when we meet at 10 o'clock, unless we hold the Session beyond the ordinary time for adjourning, namely, to 1 o'clock in the afternoon. I trust the good sense of this Association will see to it that its business shall be attended to, and it can be done if the members are prompt, are here in proper time, and give three hours to the General Session each day for the purpose of transacting the business that comes before the Association. You know, Mr. President, we have the Presidential Address; we have other addresses to come before us, and as illustrated yesterday, it is impossible for us to get through with our business satisfactorily and intelligently. (Applause.) (Cries of Question! Question!)

Dr. Dudley S. Reynolds of Louisville, Ky.—I am as much interested in the Section work as anybody in the Association, likewise in the general prosperity of the whole body. If the recommendations of our Business Committee, to whom we commit all the details of our business that my distinguished and venerable friend from Maine referred to are carried out, then we will have no need for three hours every day in General Session. If we adopt the amendment suggested by the gentleman from Pennsylvania, the first day being the most important one, when the largest amount of business is required to be transacted, on that day we will have three hours; that is, meet at 10 o'clock and continue, if necessary, until 1. On subsequent days I am sure that 11 o'clock is quite early enough for the General Session. It will enable the Sections to have two good hours of work in the forenoon; it will, at the same time, spur us up and make us prompt in the discharge of our duties in reference to executive business when we meet in general session. I move the adoption of the resolution as amended. Seconded and carried.

The President.—The next item is with reference to a resolution, to be presented by Dr. Dudley S. Reynolds.

The Permanent Secretary read the resolution as follows:

WHEREAS, The AMERICAN MEDICAL ASSOCIATION did at Detroit, 1892, unanimously resolve to demand of all the medical colleges of the United States the adoption and observance of a standard of requirements of all candidates for the degree of doctor of medicine, which should in no manner fall below the minimum standards of the Association of American Medical Colleges, and whereas this demand was sent officially by the Permanent Secretary to the Deans of every medical college in the United States and to every medical journal in the United States.

Now, therefore, the AMERICAN MEDICAL ASSOCIATION gives notice that hereafter no professor or other teacher in, nor any graduate of any medical college in the United States, which shall after January 1, 1899, confer the degree of doctor of medicine or receive such degree on any conditions below the published standard of the Association of American Medical Colleges be allowed to register as either delegate or permanent member of this Association.

Resolved, That the Permanent Secretary shall within thirty days after this meeting send a certified copy of these resolutions to the Dean of each medical college in the United States and to each medical journal in the United States.

The resolution was seconded by Dr. Parke Ritchie of Minnesota. (Referred to the Business Committee.)

The Permanent Secretary said he had received a communication from the Board of Trustees by Dr. Preuch Stone, which was referred to the Business Committee without being read.

14 W. Ohio St., INDIANAPOLIS, IND., June 3, 1898.
To the Business Committee of the AMERICAN MEDICAL ASSOCIATION.

Sirs:—The proposition to adopt a distinctive, attractive and permanent badge to designate members of the AMERICAN MEDICAL ASSOCIATION, which has grown to be one of the most powerful and influential scientific organizations in the world, is hereby respectfully presented for favorable consideration during your next annual meeting at Denver, Col. This proposition has been discussed among members of the Association for many years, and the preponderance of expressed sentiment is that some method of recognition when they meet by chance as well as on social and professional occasions, is a necessity. The newspapers and the medical press have also encouraged the use of some suitable emblem which should be constantly and conspicuously worn, not only for the above purpose, but as a means of professional identity in cases of emergency and acci-

dents that may aid in saving life. It is true that we have many men of our profession holding official position in the organization, and otherwise distinguished, for whom in some particulars medical insignias are of less benefit than to the vast majority of its members of good standing who pay their annual dues and aid in other ways in maintaining the strength and influence of the Association. These men are not only entitled to some method of making known their connection with the organization, but would greatly appreciate the privilege of wearing an emblem that had been approved and adopted as a permanent badge, indicating worthy membership of our National Association. It is also believed that if such an emblem were adopted that other medical men throughout the country would be inclined to become permanent members of the organization, and thus aid in giving it additional financial as well as numerical strength. And we can readily see how the wearing of such means of permanent identification might be of much service in arousing a spirit of fellowship that would be helpful in bringing the members of the Association closer together. "It would serve to fix attention and direct thought to the interest of the Association during the intervals between the annual meetings and would prove suggestive of matters pertaining to its growth and development." To meet this requirement I herewith send you for consideration and adoption what is believed to be an appropriate gold and enameled finished emblem. Please observe that the device is in the form of a circular shield, having for its central feature a spear-pointed cross, opposite to the arms of which are the initial letters of "Members of American Medical Association." The circular shield and spear-pointed cross typify the protective armor of the period in which medicine had its origin. The cruciform center not only typifies the great advancement of the profession during the Christian era, but was also the ideographic sign or symbol of life and of the "Healing Art" in ancient Egypt, Greece, Rome and other nations of the greatest antiquity. The initial letters and enameled National colors (red, white and blue), sufficiently symbolize the Nationality of our Association. For these reasons it is believed that the design represents the origin, history, traditions and province of our profession, as well as National character of our organization in the fullest sense, and that the emblem constantly worn as an ornate coat lapel button (or scarf pin), would serve at all times and upon all occasions throughout the world as a distinctive method of social and professional recognition, thus securing the many advantages resulting from this identity.

In order that this badge proposed for the exclusive use of members of the Association should not be obtained or worn by any one except a member of the Association, I have obtained letters patent for the leading feature of the design which confers the exclusive right to make, use and sell the emblem throughout the United States and Territories thereof, and I desire it to be furnished to members only, through the official representative of the Association.

I further agree that in case this badge is adopted and it is desired by the executive committee that the patent right in it become the exclusive property of the Association to assign and transfer my whole right, title and interest in and to the said design for the badge and in and to the letters patent therefor aforesaid, as well as in and to the tools for manufacturing the aforesaid badge, now in the hands of Irons & Russell, of Providence, Rhode Island, and herewith send the legal papers necessary to such agreement, as well as a written proposition from the aforesaid Irons & Russell to manufacture the insignia, either in enameled rolled plate or solid gold, on unusually reasonable terms that will only confer considerable revenue to the Association.

Hoping that the foregoing proposition will meet with favorable action in securing the adoption of this emblem as a permanent badge by the Association during its present session.

Yours very truly,

RICHARD FRENCH STONE.

Referred to the Business Committee.

Dr. W. W. Keen of Philadelphia offered the following resolution:

Resolved, That a committee of five be appointed by the President, at his leisure, to co-operate with similar committees from other bodies to consider the desirability of formulating plans for the dissemination of knowledge of the value of experimental research in the progress of the science and art of medicine.

Seconded by Dr. Dudley S. Reynolde and referred to the Business Committee.

Dr. William H. Humiston of Cleveland, Ohio, read the report of the special committee on National legislation to the Ohio State Medical Society, May 5, 1898, as follows:

To the President and Members of the Ohio State Medical Society:

GENTLEMEN:—Your committee on National legislation appointed in response to the overture of the New York State Medical Society, has awaited the call of the committee of that society for a meeting in Washington to perfect a National organization, but so far no call has been received. Copies of the resolutions of this society anent the antivivisection bill of Senator Gallinger, still pending, were sent by your chairman to Dr. Busey, chairman of the District Committee of the District of Columbia, and likewise to Senators Foraker and Hanna. Your committee received a reply from Senator Foraker, and a promise to give your request a favorable consideration, but no reply has so far been received from Senator Hanna. The District Committee, however, caused your resolutions to be printed and placed in the hands of every member of the Senate. Apparently, if we may judge from the circular letter sent out recently by Dr. Howard Kelly of Baltimore, Senator Gallinger is still obstinate in his determination to override the all but unanimous sentiment of the medical profession, and to push the enactment of his mischievous measure into law, but up this time, owing, in no small degree, to the efforts of the Society, he has not yet succeeded in bringing it to a vote, but the antivivisectionists are persistent; they have ample means and time at their disposal; they have able and influential advocates resident in Washington, and the medical profession must also have its men on the ground, acting with full authority delegated to them in order to counteract the effects of the so-called humane organizations to hamper and hopelessly cripple physiologic and biologic investigation in the Government laboratories and in the Medical Schools of the District of Columbia.

It seemed to your Committee, last year, that the New York plan provided for too large a body—a body, which from its very size, would prove too unwieldy for prompt and effective work—but the need of a body which shall authoritatively represent the organized medical profession upon those matters of legislation regarding which the medical profession alone has the requisite training to speak with the proper authority, becomes increasingly evident, and your Committee beg leave to submit the following plan of organization for the consideration of the Society.

1. That the AMERICAN MEDICAL ASSOCIATION be requested to appoint a standing committee of three on National legislation; one member to be a resident of Washington; one, of Baltimore; and one, of Philadelphia. A Committee so located could be called together at Washington on short notice, and appear before the committee of Congress at any time.

2. That each State Society of legally qualified practitioners of medicine be requested to appoint a committee of one on National legislation; such committee to keep himself in communication with the Senators and Representatives from his own State, so that they may be always kept in touch with the medical profession concerning matters of sanitary and medical legislation.

3. That a joint meeting of the Committees of the AMERICAN MEDICAL ASSOCIATION, and of the committeemen of the several States be held in Washington, subject to the call of the Committee of the AMERICAN MEDICAL ASSOCIATION. The purpose of that meeting would be to give opportunity for each State committeeman to personally interview the Representatives and Senators from his own State, and for the committee as a whole, or by sub-committees, to appear before the various Congressional committees to set before them authoritatively the sentiment of the medical profession regarding pending legislation, and to urge the passage of measures upon which the medical profession of the Nation have already agreed, and to which they have already given support by formal action. Meeting thus on the ground and consulting together, the members of such joint committee would, moreover, become better cognizant of matters upon which the medical profession ought to take action, and by embodying such matters in their annual reports to their respective societies, the sentiment of the medical profession as a whole would be promptly and authoritatively declared. We should then begin to act as a unit in matters of National legislation affecting the sanitary interests of the people as a whole.

4. That the necessary expenses of these committeemen be borne by their respective societies.

In conclusion, your committee would recommend further the adoption of the following resolutions:

Resolved, That we again enter our earnest protest against Senate Bill No. 1063, entitled "A Bill for the Further Prevention of Cruelty to Animals in the District of Columbia," for the reason that existing laws amply provide for the prevention and punishment of any real cruelty to animals which may

he proven to occur within the District, and because the physicians and scientists of the District have not so conducted themselves in the past as to warrant the system of irresponsible espionage authorized by the bill, and further, because the paramount interest of the sick and afflicted demands that the medical profession shall have liberty to investigate the nature and treatment of disease, free from cumbersome and vexatious restrictions, such as are provided in the measure in question.

2. That we again urge upon Congress the necessity of thorough inspection, by a medical officer of the United States, of all immigrants and their baggage, before they embark for this country, in order that the importation of contagious and infectious filth diseases may be more effectually prevented.

3. That the Secretary of this Society send a copy of these resolutions to each Senator and Representative in Congress from Ohio, and of the latter resolutions to the chairman of the committee on commerce and on immigration of both House and Senate.

Respectfully submitted.

L. B. TUCKERMAN,
RUFUS B. HALL,
A. M. BLEILE.

Committee.

The report was recommended for adoption by the Business Committee, and unanimously adopted by the State Society.

Referred to the Business Committee.

Dr. H. A. Hare introduced the following resolution:

WHEREAS, In time past circumstances have occurred which have deprived this Association of the presence and co-operation of many members of the profession of high standing who have contributed much to the advance of medicine and surgery.

Resolved, That the AMERICAN MEDICAL ASSOCIATION invite the New York Medical Society, the New York County Medical Society, the New York Academy of Medicine and other societies of good and regular standing to send delegates to this Association who will be received and accredited upon proper credentials from the officers of such societies.

Resolved, That all actions and ordinances of this Association contrary to this resolution in spirit or letter are hereby rescinded.

Referred to the Business Committee.

The Permanent Secretary announced the Committee on Nominations, as follows:

Alabama—H. A. Moody. Arkansas—J. H. Southall. California—H. B. Ellis. Colorado—J. T. Eskridge. Connecticut—T. D. Crothers. District of Columbia—H. L. E. Johnson. Georgia—E. T. Connelly. Illinois—T. J. Pitner. Indiana—J. H. Oliver. Idaho—E. E. Maxey. Iowa—W. D. Middleton. Kansas—James A. Lane. Kentucky—J. N. McCormack. Louisiana—Randell Hunt. Maine—M. C. Wedgewood. Massachusetts—H. O. Marcy. Maryland—J. B. Blake. Michigan—H. O. Walker. Minnesota—A. J. Stone. Missouri—I. N. Love. Montana—C. K. Cole. Nebraska—G. H. Simmons. New Jersey—Alexander McAllister. New Mexico—W. R. Tipton. New York—E. D. Ferguson. North Carolina—J. A. Burroughs. North Dakota—H. Wheeler. Ohio—J. E. Cook. Oregon—J. S. Moore. Pennsylvania—H. M. McConnell. Rhode Island—E. D. Clark. South Carolina—J. L. Dawson. Tennessee—G. C. Savage. Texas—John O. McReynolds. Utah Territory—S. Ewing. Vermont—E. R. Campbell. Virginia—L. B. Edwards. West Virginia—A. L. Huff. Washington—J. B. Eagleson. Wisconsin—W. H. Earles. Wyoming—R. Harvey Reed.

United States Marine-Hospital Service—J. M. Gassaway.

The Army and Navy of the United States—Drs. W. P. Munn and A. L. Gihon.

Alaska, Arizona, Delaware, Florida, Indian Territory, Mississippi, Nevada, New Hampshire, Oklahoma Territory and South Dakota are not represented.

The Permanent Secretary read telegrams from Drs. Nicholas Senn, Donald Maclean and F. H. Wiggin, regretting their inability to be present.

The following communication was read from Dr. Horner relative to the Medical Aid Association:

LIST OF SECRETARIES OF STATE MEDICAL SOCIETIES.

I. R. Wellington, District of Columbia; I. R. Jordan, Alabama; G. A. Archman, Whceling, W. Va.; W. F. Amos, Portland, Ore.; I. W. Cokenower, Des Moines, Iowa; D. C. Hawley, Burlington, Vt.; W. G. Townsend, Baltimore, Md.; N. E. Wordin, Bridgeport, Conn.; Ignatius Donnelly, St. Paul, Minn.; F. W. Goss, Roxbury, Mass.; P. W. Tomlinson, Wilmington, Del.; C. D. Smith, Portland, Me.; W. C. Riddell, Helena, Mont.; F. T. Rogers, Providence, R. I.; Steele Bailey, Stanford, Ky.; C. R. Atchison, Nashville, Tenn.; G. H. Simmons, Lincoln, Neb.; T. Hubbard, Toledo, Ohio; W. F.

Cheney, San Francisco, Cal.; F. H. Coe, Seattle, Wash.; H. A. West, Galveston, Texas.

The above list of Secretaries of twenty-one States of the Union is made in accord with the resolutions unanimously adopted and endorsed by the Medical Society of Pennsylvania at the meeting of the AMERICAN MEDICAL ASSOCIATION in Philadelphia, viz:

Your committee would respectfully recommend that the Association which will assemble at Denver, Colo., will appoint a sub-committee and nominate a President of an American Medical Aid Association, Secretary, Treasurer and Corresponding Secretary, and will invite Fellows of the AMERICAN MEDICAL ASSOCIATION to contribute a sum of two dollars per annum to raise a sum to be used for the relief of disabled physicians and the widows and orphans of said Fellows, members of the American Medical Aid Association, when application is made for such relief. Respectfully submitted by Chairman of Committee.

May 13, 1898.

P. A. Surgeon U. S. Navy (Retired).

Dr. L. J. Lautenbach of Philadelphia offered the following resolution:

WHEREAS, Errors in Public School Text-books treating of Physiology, Hygiene, Chemistry and other subjects allied to medicine are prone to cause not only misapprehension and doubt but may occasion serious damage to the life, health and welfare of the community, and it having been proven that such errors exist in greater or less number in such works, therefore be it

Resolved, That the President of the AMERICAN MEDICAL ASSOCIATION appoint a committee of five who shall be empowered to examine all such works and finding such errors communicate with the authors and publishers of the same with the view to their elimination and report their results to the society annually.

Referred to the Business Committee.

Dr. Marcy of Boston, offered the following:

Resolved, That the Secretary hereby request the various State medical societies to so change the date of their annual meeting so as not to conflict with the date of the annual meeting of the AMERICAN MEDICAL ASSOCIATION.

Seconded and carried.

Dr. W. H. Sanders of Mobile, Ala., offered resolutions in regard to the public health, which were referred to the Business Committee.

At the conclusion of the resolutions, Dr. Sanders said: Mr. President, I move the adoption of these resolutions as an expression of the opinion of this body upon the matters which the resolutions bear. Seconded and carried.

Dr. William Bailey of Louisville, Ky.—I have a short preamble and resolution which I desire to read and ask their reference to the Business Committee.

WHEREAS, The business of the Association has increased so greatly that it is difficult to have it all performed in a satisfactory manner under the existing arrangements;

WHEREAS, New lines of operation have been opened which it is desirable to follow;

WHEREAS, It is believed that with an active Secretary, who could devote his whole time to the work, very material advance could be made in extending the operations and increasing the usefulness of the Association, with a great increase in its membership; therefore, be it

Resolved, That a General Secretary be appointed by the Business Committee at a salary not exceeding \$3000 per year, who, under the direction of the Business Committee, shall forward the interests of the Association in every way possible.

Resolved, That the present Permanent Secretary be retained with the title of Honorary Secretary, with the present salary.

Resolved, That the Business Committee be directed to consider the matter and report to the Association in regard to the feasibility of the plan proposed.

Referred to the Business Committee.

Dr. George M. Gould of Philadelphia, offered resolutions as follows, which were referred to the Business Committee:

WHEREAS, The establishment, organization and filling of public medical libraries is a means of vast and increasing importance both for the preservation of medical literature and the progress of medical science; and

WHEREAS, There are at present but very few such libraries in the United States, and of these, the great majority are in a sad state of imperfection and inefficiency; and

WHEREAS, Most valuable literature is wasted because of the non-existence or imperfection of such libraries; it is therefore

Resolved, That the AMERICAN MEDICAL ASSOCIATION unanimously approves of any ethical and legitimate methods of encouraging the organization, perfection and support of public med-

These resolutions have not been received by the JOURNAL.

ical libraries in all the cities, towns and villages of the United States, and earnestly urges the members of the Association to aid in the formation and organization of such libraries; also

Resolved, That the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION be sent gratis to the membership libraries of the Association of Medical Librarians, or to other libraries that may be recommended by the Executive Committee of said Association.

Dr. H. A. Hare of Philadelphia—Mr. President, I rise to a point of order.

The President—Please state your point of order.

Dr. Hare—In your decision concerning an important resolution which I offered a few minutes ago, the resolution was referred to the Business Committee. As far as I can learn, sir, that reference is incorrect.

The President—Do you appeal from the decision of the Chair?

Dr. Hare—I do, sir.

The President—Dr. Hare of Philadelphia, appeals from the decision of the Chair in regard to the reference of his motion or resolution. The question before the Association is, gentlemen, shall the decision of the Chair be sustained? Those who favor sustaining the Chair in reference to the resolution offered by Dr. Hare in regard to the New York State Medical Society will signify by saying aye; contrary minded, no.

[The Chair was sustained in his ruling.]

Dr. H. M. McConnell of Pennsylvania—I move you, sir, that Dr. Hare's resolution be taken from the Business Committee. Seconded. (When the Chair put the motion of Dr. McConnell the ayes were so feeble that a division was called for. The result was that 104 were in favor of taking the resolution from the Business Committee, and 116 against.)

The Permanent Secretary read the following resolution, offered by Dr. Albert L. Gihon:

Resolved, That the Permanent Secretary as soon as possible after adjournment be requested to communicate with the Secretaries of State and Territorial medical societies to nominate their representative members on the Rush Monument Committee, and to report as soon as possible in order that the names may be announced in the JOURNAL of the ASSOCIATION. Referred to Business Committee.

The President—The next thing in order is the disposition of amendments to the Constitution and By-Laws. The first one to take action on is that offered by Dr. W. L. Wills, and I will ask the Secretary to read it.

The Permanent Secretary read the following: Article IV.—Officers. Amend to read: "Each officer shall hold his appointment for one year, and until another is elected to succeed him."

Dr. W. L. Wills of Los Angeles, Cal.—Mr. President, I wish to offer an amendment to the amendment to make the matter more easily and clearly understood, so as not to interfere with the tenure of office of members of the Judicial Council or of the Board of Trustees, whose term of office is provided for in another place in the Constitution. I would like to insert these words: "Each officer, except members of the Judicial Council and Board of Trustees, shall hold his appointment for one year, and until another is elected to succeed him." Seconded.

Dr. L. Duncan Bulkley of New York—May I ask whether this amendment to the amendment affects the members of the Business Committee.

Dr. Wills—There is no intention of interfering with the tenure of office of any permanent committee.

Dr. William T. Bishop: Mr. President, no matter what the object intended to be accomplished may be, there is one thing in regard to the written letter, namely, that it only means what is written, and not what is understood. The offerer of this amendment does not understand what he wants himself nor does he understand, it seems to me, his own amendment which he made to his previous amendment. I would suggest, to make it definite and to prevent any confusion, that the names of the President, Vice-Presidents, Secretary and Treasurer be included. Let the members understand what we are voting for. They are the officers it is intended to hit. I am opposed to the amendment unless it is expressed in that way.

The President—Are you ready for the question of the amendment to the amendment? Your vote will carry with it the suggestion offered by the gentleman from Pennsylvania, who

Dr. Daniel R. Brower of Chicago—The Business Committee excepts the Judicial Council, the Board of Trustees and the Business Committee.

has just appointed a Prize Committee. What becomes of it?

The President—That will depend upon what action is taken.

Dr. E. D. Ferguson of Troy, N. Y.—Hardly any of us know what we wish to do in regard to this matter, and I therefore move that the whole question be laid upon the table. Seconded and carried.

The President—The next item is the amendment offered by Dr. H. B. Ellis of California, which I will ask the Secretary to read.

The Permanent Secretary then read the following:

Article IX.—Conditions for Further Representation. "Any State or local medical society, or other organized institution, whose rule, regulations and Code of Ethics agree in principle with those of this Association, may be entitled to representation on the advice or agreement of the Judicial Council."

Dr. Dudley S. Reynolds—I move the adoption of the amendment. Seconded.

Dr. X. C. Scott of Cleveland, Ohio—This is a very serious question for the Convention to consider. In the event of our meeting in large cities, it will be possible to form enough medical societies where they can send enough delegates to control the legislation of this body. Mr. President, this question has come up year after year, and each year it has been voted down. Therefore, Mr. President, I move that this amendment be laid upon the table. Seconded and carried.

The following amendment was read and adopted:

"That the name of Section on Dental and Oral Surgery be changed to that of Section on Stomatology."

The Permanent Secretary read the following amendment offered by Dr. L. Duncan Bulkley:

"That all new business shall be introduced not later than the third day of the session."

Dr. X. C. Scott—I move its adoption. Seconded.

Dr. W. T. Bishop—I move as an amendment that the following words be inserted, "unless there is objection." This will accomplish the same thing and will keep us from being tied up. Seconded.

The motion as amended was put and carried.

Dr. J. H. Mueser of Philadelphia then read the Oration in Medicine.

On motion, the Association adjourned until 11 A.M. Thursday.

JUNE 9—THIRD GENERAL SESSION.

The Association met at 11 A.M., and was called to order by the Fourth Vice-President, Dr. Happel of Tennessee.

The Permanent Secretary read the minutes of the previous general sessions, at the conclusion of which Dr. A. L. Gihon said: I certainly object to the statement in the minutes that I offered the resolution which the Secretary says I did. The resolution offered by me concerned another matter which he has not read. The resolution I offered was to this effect, that the Secretary communicate with the secretaries of the State and Territorial societies with respect to nominating representative members for the Rush Monument Committee, and that those names be published in the JOURNAL of the Association.

The President—I believe Dr. Lane, of Kansas, offered a resolution making Dr. Munn of the army, and Dr. Gihon of the navy, members of the Nominating Committee. The Secretary will make these corrections.

The President—The next matter to come before the Association is the report of the Board of Trustees, which will be read by Dr. Garcelon of Maine.

Dr. Garcelon then read the report as follows:

REPORT OF THE BOARD OF TRUSTEES.

MEMBERS OF AMERICAN MEDICAL ASSOCIATION: In submitting the present report at the 49th annual meeting of the AMERICAN MEDICAL ASSOCIATION, and the 15th year since the change from a yearly publication of the Transactions of the Association to the establishment of a weekly Journal, entitled "THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION," the Trustees take pleasure in congratulating you upon the success which has attended the Association in whatever light examined. Organized originally especially for the purpose of elevating the standard of medical education, it has steadily kept that object in view, and we have great pleasure in noting that a large number of our leading medical institutions have not only lengthened the curriculum of their instructions, but have demanded higher qualifications of those preparing to enter the ranks of the profession. The importance of a liberal education is becoming more and more noticeable, and we trust that the day is not far distant when every young man who seeks to qualify himself for the most important position that the needs of human society demand, will not only be able to acquire a satisfactory preliminary education, but to pass such an examination as only a first-class college course may require. Aside from this, there can probably be no better method desired in a country of so vast an extent as this to cultivate friendly social relations and that *esprit du corps* which ought to exist between the members of every liberal profession, and we shall be sorry to see the day when these annual gatherings come to be looked upon with indifference.

In 1883, when the experiment of publishing a weekly medical journal as the organ of the Association was suggested, there was quite a large minority of our members who were decidedly opposed to such a change. They thought the annual volume of the Transactions was all that could be profitable, and besides we were feeble in membership, and without funds to purchase material, or meet the current expense of rent, type-setting, proof work, stitching and other necessary machinery or material, saying nothing of paper and type, without which nothing could be accomplished. Aside from this, where was the enterprise to be started? The members east of the Alleghenies thought they occupied the citadel of medical lore, and that as Washington was the seat of government it would, and by all means it should, be the point in that vicinity. On the other hand it was urged as the Association was of a national character, a more central point should be selected, and all things considered, either Chicago or St. Louis should be selected and the fact that Chicago took the lead in point of population and was likely to do so for a period of years at least, that city was selected for the purpose.

The first number of Vol. 1 was issued July 1, 1883, and 3,500 copies of that date were struck off, being largely in excess of the membership of the Association, hoping by sending copies to physicians outside of membership, many might be induced to become members, or at least subscribers for the JOURNAL. At that time the membership of the Association, including both delegates and permanent members, did not exceed 1,500. For the five succeeding years the increase of membership was not large, there being during the year 1887 only an increase of 61. Since that time, that is, during the past decade, the increase of membership, as well as of the general circulation of the JOURNAL has rapidly increased.

The circulation for the year 1897 was:

January 2	7,600	July 3	8,600
January 9	7,700	July 10	9,000
January 16	7,800	July 17	8,900
January 23	8,500	July 24	8,950
January 30	8,500	July 31	9,000
February 6	8,500	August 7	9,000
February 13	8,000	August 14	9,100
February 20	8,500	August 21	9,025
February 27	8,700	August 28	9,050
March 6	8,700	September 4	9,000
March 13	8,700	September 11	9,000
March 20	8,700	September 18	10,050
March 27	8,600	September 25	10,100
April 3	8,400	October 2	10,200
April 10	9,500	October 9	10,200
April 17	8,500	October 16	10,200
April 24	8,750	October 23	10,000
May 1	8,750	October 30	10,000
May 8	8,600	November 6	10,000
May 15	8,600	November 13	10,000
May 22	8,500	November 20	10,000
May 29	8,600	November 27	10,500
June 5	8,500	December 4	10,700
June 12	9,000	December 11	10,700
June 19	8,300	December 18	11,000
June 26	8,400	December 25	11,000

220,900

253,275

First six months of 1897 weekly average was 8,496; second six months of 1897 weekly average was 9,741; total weekly average for year was 9,118½.

The growth since last autumn has been remarkable, thus:

The regular weekly issue of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION from October, 1897, to May, 1898 inclusive, a period of eight months, was as follows:

WEEKLY EDITION.		WEEKLY EDITION.	
October 2	10,200	February 5	10,000
October 9	10,200	February 12	9,800
October 16	10,200	February 19	10,400
October 23	10,000	February 26	9,850
October 30	10,000		40,050

	48,400		41,900
	182,900		178,400

Grand total, 361,300; weekly average, 10,323.

The appearance and general character of the JOURNAL is highly satisfactory, but we are by no means content without showing continual advancement. We have carefully examined other weekly medical journals published in this country and have compiled the following instructive table:

FIVE WEEKLY MEDICAL JOURNALS—SIX MONTHS' ISSUE.
(Comparative statement of matter published.)

July to December, 1897.	Original articles.	Separate titles.	Illustra- tions.	No. pages.		Composi- tion—cms.
				Read- ing.	Adv.	
Boston Med and Surg. Jour.	135	829	72	692	872	1,209,088
New York Medical News	137	1,139	114	838	480	3,097,717
New York Medical Journal	107	1,076	173	888	1,006	2,903,316
New York Medical Record	187	1,483	100	932	1,095	3,614,846
Journal American Med. Association	280	1,510	226	1,272	692	5,313,504

This table shows conclusively that the members receive more for their money in amount of reading matter than in any other journal, and we may without fear of unfavorable result compare our JOURNAL in point of literary and scientific qualities to any regular weekly published in any part of the world.

Viewed as a newspaper, it now undertakes to publish everything in current news that will interest the physician, assist him in his daily work and defend him against outside malice. The legitimate expenses of such a journal must necessarily be large, and as its pages increase they will annually become larger. The rule of the ASSOCIATION whereby all proprietary articles must publish their formula, containing the name and amount of each ingredient every issue, causes a loss to the JOURNAL of from \$8,000 to \$10,000 annually, a loss which other journals are not compelled to sustain. That the JOURNAL has succeeded and continues to succeed in spite of this immense limitation of advertising, is complimentary to the ability, tact and foresight of the editor, who, under the direction of this Board, made the JOURNAL more and more successful each year.

The financial statement is as follows: Report of the JOURNAL for the fiscal year ended Dec. 31, 1897.

RECEIPTS.

\$47,140.07

The following is an inventory of the JOURNAL property.

Mechanical Department.—Three Miehle cylinder presses, 1 Crocker Wheeler 10 H. P. motor, 1 pony Gordon press, 1 Sheridan auto. cutting machine, 2 folding machines, 4 imposing stones, 1 stitching machine, 100 make-up galleys, 14 case racks, 2 banks (make-up tables), 1 sort cabinet, 1 type cabinet, 3 type racks, 2 kitchen tables, 4 bindery tables, 11 high chairs, 9 kitchen chairs, 1 high back oak chair, 4 fonts "body type" about 4,000 lbs., 5 pr. new chases, 1 proof press, 90 fonts job type, 200 mailing galleys, 1 pr. large scales, 1 walnut desk, 150 lbs. leads, 1 oak wash stand.

Office Department.—Two roll top desks, 2 flat top desks, 1 letter filing cabinet, 1 oak book case, 2 "Victor" safes, 6 revolving office chairs, 1 typewriter desk, 1 wire rack for exchanges, 1 P. H. box case, 1 12-ft. walnut table, 1 dictionary stand, 11 oak chairs, 2 Munson typewriters (one poor).

GENERAL FINANCIAL STATEMENT.

The report of the Association Treasurer shows the total receipts for the year ending Dec. 31, 1897, to have been \$64,522.78 and the expenditures \$25,637.67, and the balance \$14,092.72. The balance on hand was so satisfactory in amount that the Board directed an additional \$10,000 to be placed to the credit of the investment fund created by the Association in 1896 for the purpose of providing a permanent building for the home of the JOURNAL. This fund now amounts to \$13,000.00, and if the Association continues to be economical, we shall very soon reach the amount required to erect a safe and convenient building adapted for the purposes of the JOURNAL for many years to come. The Trustees were very materially aided in the accomplishment of this very desirable result by the generous action of the Philadelphia profession, who by their local Committee of Arrangements returned the \$1000 appropriated for places of meeting of the General Sessions and the Sections.

INCORPORATION.

In accordance with the recommendation of this Board, approved by the Association at its last session, the Board of Trustees has become an incorporated body, and now have a definite standing as a legal incorporation.

In conclusion, the Board respectfully recommend that each member of the Association make renewed effort to help along the growing membership, by encouraging subscriptions, and membership applications, in order that by increased circulation and support we may still further extend the good influences of the Association for the advancement of useful knowledge, and the general welfare of the profession.

A. GARCELON,
 J. M. MATHEWS,
 I. N. LOVE,
 G. C. SAVAGE,
 JAMES T. PRIESTLEY,
 JOSEPH EASTMAN,

Board of Trustees.

Dr. Dudley S. Reynolds of Louisville—1 move that the report of the Board of Trustees be received, printed in the JOURNAL, and a vote of thanks extended to Dr. Garcelon for having presented it. Seconded and carried.

The President—Dr. Gihon desires to make a one-minute report, and we will now listen to him.

Dr. A. L. Gihon—I will read from my seat. I shall not occupy more than two or three minutes of your time. I am requested by the donors on part of the Rush Monument Committee to make the following statement: I have received from Dr. Haggard of Tennessee, on account, \$130; from Dr. Wingate of Wisconsin, \$78 on account; from Dr. Humiston of Ohio, \$336.25, the balance will be given at Columbus; from Dr. Cole of California \$110; from Dr. Cantrell of Texas, \$36.50; from Dr. Hare of Pennsylvania, \$186.50, in addition to the \$2000; from Dr. Wordin of Maine, \$100 on account. I have nearly \$12,000 in my hands toward the Rush Monument Fund. With all respect to my friend, Dr. Connor of Detroit, this is not rot, but fructifying seed, which has borne good fruit. (Applause.)

The President—The next item will be the report of the Committee on Public Health, which will be read by the Chairman, Dr. U. O. B. Wingate of Milwaukee, Wis.

Dr. Wingate, as Chairman, then read the following report:

REPORT OF SPECIAL COMMITTEE ON DEPARTMENT OF PUBLIC HEALTH.

Mr. President and Members of the Association—In 1891 the following resolution was adopted:

"Resolved, That the President of this Association appoint a Committee of five to memorialize Congress, at its next session, on the subject of creating a cabinet officer to be known as a medical secretary of public health." This Committee was appointed and has been in existence ever since. Its personnel has been changed from time to time. In the argument set forth preliminary to the formation of this Committee it was claimed that "there is no other profession that excels us in positive efficiency to sustain public order, comfort and happiness. We possess vast capacity for the direction of society and promotion of human happiness. There is nothing in the body or mind of man that is not the purview of medical practice. We are laboring unceasingly to assuage all illness of individuals and communities. At this time the profession is manifesting, in a higher spirit than ever before, the purpose of suppressing contagious and infectious diseases. This work has begun by Jenner a century ago, and the awful scourge of small-pox has been stamped out wherever vaccination is compulsory. We have now assumed the task of suppressing all the terrible diseases that desolate the world. There are infectious and epidemic diseases that move about the world almost periodically, which we need not particularize. They are often the products of equal and wretchedness of peoples, and are spread far and wide about the lines of commerce. These invisible foes of human health infest the air, water, and the very food we eat. From the grosser foes of human health, cold, heat and tempest, men have power to defend themselves, but in regard to these invisible agents of suffering and death for want of higher knowledge they are largely helpless. In their despair they turn to medical science for help, unwilling to trust in the brute law of the survival of the fittest.

"Governments, in a certain way, have always done something to aid medical men in their endeavors to stay pestilence and save the afflicted, but never adequately. They have generally refused to make the medical profession a permanent integral part in the administration of the State, that is, in the making and execution of sanitary laws."

This argument goes on and defines what laws are necessary for the full employment of our beneficent profession, and affirms that all the measures for public relief on these important subjects should be under the guidance of medical men. It sets forth that the medical profession holds itself ready, not only to diminish the fearful destruction of life now going on, but ultimately to destroy the contagia that cause it. It refers to the latest addition to the cabinet of the President, that of secretary of agriculture, and sets forth that a secretary of public health will be of the greatest importance to the welfare of the nation, and finally the "unification of all things relating to public hygiene in the States through the aid of the State boards of health will give a solidity and usefulness to the practice of medicine never hitherto attained."

In 1892 this Committee made its first report under the chairmanship of the late and lamented Dr. C. G. Commenge. A "petition to the extent of eight thousand copies was printed in pamphlet form and issued within the covers of the JOURNAL of the Association; a large number were sent out at the request of State boards of health and others; a sufficient number placed in the hands of members of Congress. Copies were also sent to all medical schools of the Union, and a large number of favorable responses were received from physicians in the States, east, west, north and south; from some of our eminent schools of learning, and from State boards of health everywhere.

"The petition, with the Bill formed to carry out its purpose, was presented in the first week of the session of Congress, in the Senate by the Hon. John Sherman, and in the House by the Hon. John A. Caldwell, both of whom warmly expressed their belief that the measure is one of great public importance and that they would do all they could to secure its adoption."

The chairman of the Committee went to Washington and was invited to meet the committees of both Houses for a conference on the subject. The report states that the chairman believes, "that in the House committee a favorable impression was made, but in the Senate committee I found the chairman quite unfavorable to it, because, and he gave no other reason to me, the present Congress would do nothing to

increase departmental expenditures." The chairman made a long and full argument before these committees, but the Bill did not pass.

In 1893, the Committee reported again, and in the report the following appears: "The members of the House committee seem disposed to favor such a department, the chairman of it saying that he thought the health of the people was certainly of as much consideration as that of cattle, which was so expensively investigated by the agricultural department. But the first session of the Fifty-second Congress adjourned and no report had been made by either House. In the meanwhile the development of cholera in Europe, and the menace of its transportation to our shores lead to a renewed activity and grant of power to the quarantine office that made it impossible to secure any further action of Congress on the proposition to establish a department of public health. Your Committee entertains most favorable opinions in regard to the activity and intelligence which is displayed by the Marine-Hospital Service for the preservation of our seaports from epidemics of foreign origin, and for its regulations to prevent their transportation from State to State along our commercial lines, but it does not seem reasonable that all the benign measures of preventive medicine should be administered by a single organization, whose function relates to so limited a field in comparison with one which relates to the demography and hygiene of cities, towns and agricultural regions of the country at large, and the supervision of which would be far more intelligent and effective by a medical secretary of state than by the secretary of the treasury."

"The difficulties attending the introduction of Bills into Congress are very serious. After the first reading they are referred to committees, where the delays are great. To be successful it requires a constant watchfulness of their progress, and members of a committee grow weary of pleas for a favorable report."

The following resolutions in addition to the report were presented: "Resolved, That this Association will continue its efforts to secure the creation of a department and secretary of public health at Washington, D. C. Resolved, That the President of the Association appoint ten members, representing different regions of the United States, who shall prepare as early as possible an appeal to his Excellency Grover Cleveland, to lay before Congress in his next annual message a recommendation that a department and a medical secretary of public health is a measure that is calculated to promote in a large way the public welfare. Resolved, That this petition shall be presented, as far as may be possible, by the Committee in person."

The report and these resolutions were adopted and permission was granted that the Committee increase their numbers as they might deem necessary.

In 1894, the Committee made a further report in which they state: "In the course of our efforts to secure the passage of our original Bill, which has hitherto, both at the annual session at Detroit and in Milwaukee, been laid before you, and which was introduced into the Fifty-second Congress, in both Houses, in December, 1891, we found that a strong opposition was made to its favorable report from the committees in the Senate and House of Representatives by the chief of the Marine-Hospital Service, because it seemed to him to encroach upon the function of his office as director of quarantine affairs, and that it would greatly embarrass his work. This was not intended at all by your Committee; therefore, as our Bill appeared to lie dormant in the hands of the Congressional committees, and as the dread apprehension of the entrance of Asiatic cholera through our commercial intercourse had so aroused Congress to the necessity of strengthening the quarantine service, making it apparently unnecessary to extend legislation in the direction of public health at that time, we were advised by friends in Congress to cease further efforts until the second session. At the opening of the second session, in December, 1892, it was found that one of our important friends in the House committee was ill, in fact was unable to take his seat at any time during the session. Your Committee then determined to wait the opening of the Fifty-third Congress, in December, 1893, for a renewal of our activity. In the meantime the great Pan-American Medical Congress met in Washington in September, 1893, and we took advantage of the assembly of that body of eminent medical men to bring before it the importance of the creation of a department of public health in all governments under the direction of a secretary appointed from the medical profession, who should be on a parity in the cabinet of the President with the secretaries of other departments. Our proposition was referred to the committee on State medicine and, after a most thorough discussion by eminent practitioners of different States, was adopted with but one dissenting voice.

Your Committee next, after due consultation, concluded that in order to avert the opposition of the Marine-Hospital Service, it would be wise to reconstruct our Bill so as to leave out any reference to the supervision by the secretary of public health of the quarantine service, merely referring to it as an available source of information for the general purposes of public health, on the same plan as that furnished by Surgeons-General of the Army, Navy, the State Boards of Health, and all municipalities, hospitals and asylums throughout the country. Therefore, we redrafted our petition and Bill in regard to the establishment of the public health department and the secretary of public health, and they have been introduced into the present Congress, in the Senate by the Hon. Mr. Gray of Delaware, in the House by the Hon. Mr. Goodnight of Kentucky, and have been referred to proper committees."

The report also contains the following: "Our success has been greatly compromised by the action of the New York Academy of Medicine in their endeavor to frustrate our movement by the preparation of Bills to obtain action of Congress, to extend in various ways the existing quarantine laws, and to keep the profession under the autonomy of the secretary of the treasury or the secretary of the interior, and their plan has been urgently pressed upon the attention of the State and medical societies, and State boards of health throughout the Union."

The report closes with the following: "It is not probable that any bill can pass at this session of Congress, but the Association should at this time direct that a renewed effort should be made so as to be ready to make the most powerful effort possible to secure the passage of our Bill at the next session. Such consolidated effort can only be made effective by an organized effort in every congressional district in the Union. In conclusion we beg to offer the following resolutions: Resolved, That the AMERICAN MEDICAL ASSOCIATION renews its appeal to the Congress of the United States to adopt the Bill now in its possession for the creation of a department and secretary of public health; Resolved, That the committee proceed as soon as possible to secure sub-committees in each congressional district of the country to obtain favorable action on the part of their senators and representatives for this measure; Resolved, That a committee be appointed to endeavor to secure the friendly co operation of the New York Academy of Medicine; Resolved, That a sum not exceeding \$400 be appropriated to defray the necessary expenses of the committee in carrying on their work."

In 1895 the Committee reported again, under the chairmanship of the late and lamented Dr. Jerome Cochran, in which he states: "Our facilities for doing the important work entrusted to us have been strictly limited by want of funds, the Association having failed to adopt the resolution offered last year for an appropriation not to exceed \$400 to defray the necessary expenses of the Committee, so that such expenses as we have incurred have been paid out of our own pockets." He further states, "That in December some members of the Committee visited Washington for the purpose of ascertaining just what could be done toward pushing our enterprise to a successful result. We found a good many members of Congress who promised us their co operation whenever a favorable time could be found for the consideration of our Bill, but all agreed that it would be impossible to accomplish anything during the continuance of the Fifty-third Congress." In conclusion he adds: "To this end we had prepared a resolution recommending an appropriation, but as this object has been accomplished by the action of the Association on the recommendation of the Section on State Medicine it is not necessary to offer this resolution." The report was received.

In 1896, another report of the Committee was made by Dr. Cochran, in which he states that "The Bill which was prepared for presentation to Congress was extremely crude and indefinite in its provision and gave this proposed high official very little important work to do. It was indeed found to be so defective that last year the effort to have it enacted into a law was abandoned. In the meantime the Marine-Hospital Service, which in 1890 had already been invested with some important health functions, was by the act of 1893 converted into a National Health Department with very large and far-reaching powers and abundant means. It is not called a department of public health, but is a department of public health in fact. Since 1893, until the effort was abandoned last year, our Committee has been engaged in the hopeless and unwise enterprise of endeavoring to induce Congress to establish another department of public health, a very weak and inconsiderable department by the side of a very powerful department. Such an effort could not succeed. Such an effort did not deserve to succeed." In conclusion, he says, "In arranging any scheme of national public health supervision it would seem desirable

that nothing should be done to discredit and weaken the various State boards of health, but that contrariwise the efforts should be to strengthen the State organizations and to foster and facilitate their further evolution. If this principle is conceded it is at once made evident that the national department of public health should act in and through the State boards of health, in co-operation and harmony with them and not outside of them and independent of them. If the national department acts within the States, independently of the State boards, then the State boards become comparatively useless institutions and will fall into disfavor. Some of the State boards are still weak institutions and any rivalry between them and the national department in State work will doom them to speedy destruction. In this direction it would seem that additional legislation is needed, and the simplest plan to reach the desired reconciliation shall embrace two provisions. First that the national department should act within the States by and in co-operation with the State boards. Second, that the head of the national department should call annually to meet in the city of Washington an advisory council to be composed of one representative from every State board of health. This would bring about mutual understanding and co-operation and reciprocity of action and would virtually constitute a great school of public hygiene. Such a scheme as this would probably command the approval and support of the national conference of State boards of health, which conference is quite as deeply interested in movements of this character as is the AMERICAN MEDICAL ASSOCIATION. At the conclusion of the whole argument we recommend that we be authorized to invite the co-operation of the conference of State boards of health and the American Public Health Association in our favor to have the proposed Bill enacted into a law."

"On motion, duly seconded, the report was accepted, the plan outlined adopted, the Committee continued and enlarged by the appointment of a member from each State."

In 1897, your present chairman reported that it was found impossible to get either the Fifty-fourth Congress or the special session thereof to take any action on such a measure; that he had appointed additional members of the Committee as provided for at the last meeting and that a Bill had been drafted, which was presented. The Committee recommended the continuance of the Committee with powers to have the aforesaid Bill amended to meet requirements, but not to change the general purpose thereof, and to introduce the same into Congress at its discretion. Since that time, your Committee desires to report, that it has been actively engaged in this work.

As soon as the Fifty-fifth Congress convened work was begun to prepare a Bill, or to amend the Bill submitted at the last meeting of the Association, that would meet the requirements and be most likely to pass Congress, and that would receive the support of the greatest number of the medical profession, and also one that would meet with the least opposition. This was found to be a gigantic undertaking. The chairman of your Committee went to Washington and consulted with the best men in Congress who would give him a hearing on the subject, and it was found that the great majority of members of Congress were totally ignorant of the subject and many of them were not inclined to give it the time that was necessary to become familiar with it. Others, however, required time to study it. It was found, however, that it was out of the question to find a member of Congress who would introduce a measure, even, creating a cabinet officer. The President, members of the cabinet and of Congress were opposed to creating any more cabinet offices. It was argued that there were too many cabinet offices now, and if the way was opened by considering our request other organizations would ask for the same, and it was absolutely decided by Congress and the President that this proposition could not be entertained. There was also equal opposition by Congress to creating any independent commission, and the only thing that would receive recognition was a commission or bureau to be under the supervision of some other department. The Bill was drafted and redrafted many times before we could get it in such shape as to receive the support of certain leading members of Congress. The main idea, however, of having a single medical head, to be located in Washington, and for him to have the aid of counsel from members of State health organizations from each State and Territory, as outlined in the report of Dr. Cochran two years ago and adopted by the Association, was steadfastly adhered to throughout by the chairman of your Committee, and the same was incorporated in the Bill that was finally decided upon. This idea was also endorsed by the American Public Health Association at its last annual meeting held in Philadelphia, and it is almost unanimously approved by those who have given the most attention to the question. Your chairman

believes that this feature of the Bill is by far the most vital portion of National Health Legislation that we can ask for. Before the Bill was introduced a conference was held between the chairman of your Committee and the Supervising Surgeon-General of the Marine-Hospital Service, with a view of attempting to bring about some compromise in the provisions of the Bill that would avert the opposition of that Service, but such was found impossible, and that Service would only favor the Bill which is known as the Caffery Bill, which only relates to quarantine, leaving out all attention to internal sanitation, which your Committee believes to be of far more importance than quarantine, and gives to that Service autocratic powers to control not only maritime quarantine but to go into any State or Territory and take full charge, without any voice from the local authorities either in making rules or regulations or the enforcement of such rules and regulations as that Service may see fit to adopt. This Bill, which is practically the only opponent now existing in Congress against our measure, gives autocratic power to one man, namely, the Supervising Surgeon-General of the Marine-Hospital Service, to have absolute control over all quarantine, both maritime and interstate. Your Committee found a very decided objection to this measure in Congress; on the other hand, it had some very strong supporters, the supporters believing that the Marine-Hospital Service furnishes the best foundation upon which to build a national health department.

Our Bill was introduced into the Senate by the Hon. John C. Spooner of Wisconsin, and referred to the committee on "Public Health and National Quarantine," and into the House by Hon. Theobald Otjen of Wisconsin, and referred to the committee on "Interstate and Foreign Commerce." The Senate committee refused absolutely to hear your Committee, or to give them any opportunity to be heard on the question. They had decided, with one dissenting vote, to recommend the Caffery Bill, which places the quarantine power into the hands of the Marine-Hospital Service, and all other Bills, several of which were before them, were laid aside. The House committee, however, gave the chairman of your Committee a hearing, and he was ably supported at that hearing by Dr. H. B. Horlbeck, the health officer of the city of Charleston, S. C., and Dr. A. H. Doty, quarantine officer of the port of New York. There was a division in this committee and it is doubtful how it will report to the House. In the Senate, however, it is intended that our Bill shall be offered at a proper time as a substitute for the Caffery Bill, and it is believed by Mr. Spooner, who has it in charge, and he is generally recognized as one of the ablest senators in Congress, that it stands a fair chance of passage. It is also believed that the Caffery Bill will not pass either the House or the Senate. During this time your chairman has visited Washington five times, and has been ably supported there from time to time by Dr. C. O. Probst of Ohio, Dr. Horlbeck of Charleston, Dr. Doty of New York and Dr. H. L. E. Johnson of Washington, as well as Dr. Porter, State health officer of Florida, and to whom he desires at this time to return grateful acknowledgement. He has also attended the quarantine convention held at Mobile, Ala., where the question of national legislation was discussed, and argued the question before that convention, and also went before the New York Board of Trade and Transportation, and succeeded in getting that body to support our measure.

Your chairman is pleased to report that he believes that never before has any Bill of this nature, that has been introduced into Congress, received the extensive support that the present Bill has and is receiving. It has the support of the New York Academy of Medicine, the New York Board of Trade and Transportation, the New York Chamber of Commerce and several other large business organizations in the country who are vitally interested in quarantine matters. It has received a great deal of attention from the newspapers of the country and as a general rule has been favored by them. It has, however, received some very bitter opposition by some few medical journals of the country and one sanitary journal, namely, the *Sanitarian*. This publication has been exceedingly bitter and the vials of wrath of its editor have been frequently replenished and poured out profusely, much, undoubtedly to his satisfaction, and greatly to the amusement of those who know his peculiarities. Practically there are but two Bills relating to Public Health before Congress at the present time, our own Bill and the one known as the Caffery Bill, which favors the Marine-Hospital Service, and provides that that Service shall be the health department of the country. The New York Board of Trade and Transportation, a very large and influential business organization, took a great deal of pains to learn the views entertained throughout the country concerning the matter. They addressed personal letters to nearly one thousand professional men, sanitarians and men engaged in trans-

portation and commercial pursuits. These letters contained questions relative to quarantine and solicited the opinion of these men as to the best sanitary legislation that could be asked for. "Hundreds of valuable replies were received to these inquiries and only thirteen of them endorsed the proposition to enlarge the powers of the Marine-Hospital Service. All of these thirteen letters contained the one chief argument that the Marine-Hospital Service was a good nucleus to build a National Health Bureau upon."

"On the other hand, a very large majority of the replies expressed the opinion that the National Government can never hope to create a successful national health organization based upon the Marine-Hospital Service as a nucleus, because in many States the bitter hostility to the Marine-Hospital Service, engendered by its own acts, is so formidable as to preclude any possibility of harmony between it and such State and local authorities. The opinion was that to give the Marine-Hospital Service still more arbitrary powers as proposed in the Caffery Bill, without the obligation to consult or in any way regard the local authorities, would only widen the breach, intensify the bitterness and render resort to force necessary to carry out the Marine-Hospital Service regulations." In a letter addressed to the Hon. Jacob H. Gallinger, U. S. Senator, by the President of the New York Board of Trade and Transportation he states, "The consensus of testimony before our committee was overwhelmingly in opposition to the letter and spirit of the Caffery Bill. It stamped the Bill as narrow and wholly inadequate to meet the very pressing needs of the country. The Caffery Bill exaggerates the importance of quarantine, and makes no other provision for public health protection, while advanced sanitary science pronounces quarantine to be barbarous and obsolete. The practically uniform opinion was that the country is now ready for a law which will make quarantine of constantly decreasing importance as local sanitary administration shall be stimulated and perfected. And it was very clearly shown that any law that will successfully meet the situation and needs of the country must of necessity have due regard for the wishes and views of the people, must foster and encourage good will, a spirit of harmony and co operation between States, and the national authorities and local authorities for the common well being. The Caffery Bill is the antipode of this view. It is obnoxious in its spirit, and would be more so in its enforcement, to the great mass of the American people in all the States. The Spooner Bill (which is our Bill), on the other hand, is in full accord with the most enlightened modern views of health protection. It does not abolish quarantine, but in time would bring about conditions which would make quarantine almost unnecessary. It recognizes several departments of the National Government, and every State and Territory as interested and important factors in the scheme of health protection, and gives to each a voice in the framing of health regulations, and this is done by means of organization so simple as to be immediately moved to action in emergencies. It removes friction and hostilities and promotes harmony and co-operation, which are essential to the success of any National health law. It violates no principle of national or local policy. Our Committee went over all this ground with the greatest deliberation, and although their views upon taking up the question had a decided leaning toward the proposition to give the Marine-Hospital Service the absolute and arbitrary power it asks for, they finally and unanimously reached the opinion that the passage of the Caffery Bill would be a serious injury to the people of the United States by delaying and hindering the broader, better and more certain solution of the problem which the Spooner Bill will afford."

The Bill was about to be acted upon in the Senate at the time of the declaration of war with Spain. Since then all matters of this kind have been laid aside, as is well known, and probably no action will be taken upon this matter during the present Congress. I am pleased to report that Senator Spooner, who has this Bill in charge in the Senate, and also Mr. Otjen of the House, are enthusiastic supporters of this measure. They are both strong men and will do everything in their power to have this Bill pass Congress at some future session, if not at this. I also have to state that the money appropriated by the Association has been all used and more besides, and that the Committee is sadly in need of funds to carry out this work. It is absolutely necessary that some one should be in Washington from time to time when this measure comes up for action or comes up for any hearing, as in the future, in all probability, these Bills will be re-referred to the Committee and future hearings be had. In order to have a Bill pass Congress it must be watched from stage to stage, and some one must be there to look after it and to furnish members of Congress who have it in charge with such evidence and other material as they may from time to time require. I herewith submit a copy of the

Bill as now perfected and before Congress, and most respectfully offer the following resolutions and move their adoption:

Resolved, That the Committee on Department of Public Health be continued; that the Bill as now perfected and before Congress, and which is submitted with this report, be and hereby is approved, and that the Committee be authorized to use their best endeavors to have it passed by the Congress of the United States, at such time as in their judgment it seems proper and wise.

Resolved, That the members of this Association do all in their power, by urging upon their representative members of Congress to have this Bill passed.

Resolved, That this Association appropriate the sum of one thousand dollars, or so much thereof as may be necessary, for the use of the Committee in the endeavor to have this measure passed by Congress.

Respectfully submitted,

U. O. B. WINGATE, M.D., Chairman of Committee.

Dr. Harris of New York—I move that the report be accepted and the resolutions contained therein be referred to the Business Committee. Seconded.

Dr. Bulkley of New York—I desire to say that we have no meeting of the Business Committee tomorrow, and I would suggest that the motion be so changed as to refer these resolutions to the Business Committee with power to act.

Dr. Harris—I accept the suggestion.

Dr. J. N. McCormack of Bowling Green, Ky.—I would like to move to amend the original motion by adopting the resolutions as presented by the Committee instead of referring them to the Business Committee, because they have been well formulated by the Committee, and I think we are ready to adopt them.

I therefore move that the report be received, the resolutions as read adopted, and the Committee continued. Seconded.

Dr. I. N. Love of St. Louis, Mo.—I would move that the motion be so changed as to strike out the words which give the Business Committee power to act, and report back to the Association next year. Seconded.

Dr. John B. Hamilton of Chicago—Is that motion debatable?

The President—Yes, sir.

Dr. Hamilton—Such action will simply defer this matter for one year. This Association then will be powerless to make any recommendation to Congress in regard to legislative matters for another twelve months. This Committee has been seven years in preparing this Bill and the resolutions. They are the outcome of the growth of public sentiment in respect to this question. Why then should we refer this report with the resolutions to a committee who have really no business with the subject? The Business Committee did not consider it. The Business Committee is not capable of considering so important a matter in a short time which has required this Committee years of thought and study. The State Medicine Section, a Section organized by the Health Officers in general of the States of this Union, comprises a body of men who are capable of thoroughly considering this question and they have done so. Why then should the report be postponed for another year without action when seven years have already been devoted to it. (Applause.)

The President—I will read the final resolution in regard to this report, and then it will probably solve the trouble. (Read the resolution.)

Dr. D. W. Graham of Chicago—I rise to a point of order.

The President—Please state it.

Dr. Graham—According to the Constitution and By-Laws of this Association, all appropriations of money must be referred to the Board of Trustees.

The President—The point is well made.

The President—Dr. Love moves to strike out the words "to act."

Dr. Love—I will withdraw my motion. In discussing this matter, I desire to draw the attention of the members to the fact that this Committee has been continued from year to year at the expense of the Association. The appropriation of money is contemplated in the consideration of this matter, and it does seem to me that it should be referred to the Board of Trustees who handle the money and are financially responsible. That point should be kept in mind, and I only make the point in discussing the resolution as presented by Dr. Harris.

Dr. W. T. Bishop of Pennsylvania—As this is clearly in conflict with the regulations of the Association, I move that that part of the report referring to the appropriation of \$1000 be omitted. I think the Secretary of the Business Committee is entirely off in his assumption and presumption in claiming entirely too much for that Committee. I do not think the Association, when it created this Committee, intended to turn over its whole business to a body of a dozen or two men. It was intended that this Committee should consider new resolu-

tions, and not that reports of Committees like this shall be referred to it. I raise this point against it and the motions are out of order. (Applause.)

Dr. D. W. Graham of Chicago—Mr. President, I again raise the point of order, that all appropriations of money must be referred to the Board of Trustees. I therefore move, as an amendment, that the report with the resolutions be adopted, except the provision calling for an appropriation of \$1000, and that this amount or so much thereof, as may be necessary, be referred to the Board of Trustees with power to act. Seconded.

The President put the motion as amended by Dr. Graham, which was carried.

The President—We will now listen to the report of the Committee on Nominations.

The report was read by the Chairman, Dr. H. O. Walker of Detroit, as follows:

DENVER, COLO., June 8, 1898.

Mr. President and Gentlemen of the Association.

The Committee on Nominations beg leave to present the following report:

OFFICERS.

President—Dr. Joseph M. Mathews, Louisville, Ky.

First Vice-President—Dr. W. W. Keen, Philadelphia, Pa.

Second Vice-President—Dr. J. W. Graham, Denver, Colo.

Third Vice-President—Dr. H. A. West, Galveston, Texas.

Fourth Vice-President—Dr. J. E. Minney, Topeka, Kan.

Treasurer—Dr. Henry P. Newman, Chicago, Ill.

Librarian—Dr. George W. Webster, Chicago, Ill.

TRUSTEES.

Dr. Alonzo Garcelon, Lewiston, Maine.

Dr. T. J. Happel, Trenton, Tenn.

Dr. I. N. Love, St. Louis, Mo.

To fill vacancy Dr. H. L. E. Johnson, Washington, D. C.

MEMBERS OF THE JUDICIAL COUNCIL.

Dr. S. Bailey, Mt. Ayr, Iowa.

Dr. D. R. Brower, Chicago, Ill.

Dr. N. S. Davis, Chicago, Ill.

Dr. H. D. Didama, Syracuse, N. Y.

Dr. D. Mason, Spokane Falls, Wash.

Dr. F. T. Rogers, Providence, R. I.

Dr. Milo B. Ward, Kansas City, Mo.

To fill vacancy, Dr. W. S. Jones, New Jersey.

ANNUAL ORATIONS.

Medicine—Dr. J. C. Wilson, Philadelphia, Pa.

Surgery—Dr. Floyd W. McRae, Atlanta, Ga.

State Medicine—Dr. Daniel R. Brower, Chicago, Ill.

Next place of meeting, Columbus, Ohio. Time, first Tuesday in June, 1899.

Chairman of Committee of Arrangements, Dr. Starling Loving, Columbus, Ohio. Assistant Secretary, Dr. E. W. Woodruff, Columbus, Ohio.

The following communication was received from the Board of Trustees:

The Board of Trustees hereby recommend that hereafter the local Committee shall provide free of expense to the Association, first, a hall for the general sessions; second, halls for Sections; third, rooms for committees; fourth, room for post-office and force thereof; fifth, room for registration and force thereof, and the Committee shall have the proceeds of the exhibition hall, and that hereafter this arrangement shall be agreed to by the representative of the local Committee before agreeing to a place of meeting for the Association meeting.

This communication was adopted unanimously by the Committee before selecting a place of meeting.

[Signed] H. O. WALKER, Chairman.

E. D. FERGUSON, Secretary.

Dr. X. C. Scott—I move that the report be adopted. Seconded and carried.

The President—We will now listen to a report from the Business Committee.

The Secretary of the Business Committee made the following report:

REPORT OF THE BUSINESS COMMITTEE. JUNE 9, 1898.

Your Committee would report that it has had fourteen matters referred to it by the Association, which were all fully considered by sub-committees and the Committee at large, in a very full meeting lasting several hours, and upon the matters would report as follows:

1. *President's address.*—While the Committee is fully in sympathy with the recommendations of the President as to the admission of members to the Association under the conditions mentioned, under the existing laws of the Association the Committee does not feel competent to recommend its adoption. Adopted.

2. *Report on the Rush Monument Committee's Report.*—The Business Committee commends the Committee for its efficient work in a noble cause, and expresses the hope that it may soon fully accomplish the purpose for which it was appointed.

The Business Committee approves of the nomination of H. D. Holton, M.D., of Vermont, for the office of treasurer, and recommends his election. Adopted.

3. *Rush Monument Committee.*—The Business Committee desires to report that Dr. Gihon, the Chairman, has been misinformed as to the payment of traveling expenses of the Business Committees. They receive no pay and do not ask any, and we recommend that the traveling expenses of the Rush Monument Committee be not paid. We do recommend that expenses of postage and stationery and other absolutely necessary expenses be paid.

The Business Committee recommend the acceptance of Dr. Gihon's resolution, and that the Permanent Secretary be instructed to communicate with the State and Territorial Medical Societies, asking them to nominate representative members of the Rush Monument Committee. Adopted.

4. *Treasurer's report.*—The Committee would report that so far as they can learn the report is entirely satisfactory, and the Committee would congratulate the Association on the most excellent state of its finances. As the Treasurer's accounts are under the control of the Trustees and his accounts audited by them, the Committee did not attempt any investigation or examination of vouchers. Adopted.

5. *Dr. Reynolds's resolution in regard to the Association of Medical Colleges.*—The representative to the Southern Association of Medical Colleges, representing fourteen Colleges, appeared before the Committee and assented to the action. The Committee, therefore, recommends the adoption of the resolution of Dr. Reynolds. Adopted.

6. *Dr. Lautenbach's resolution in regard to school books.*—After discussion the Committee adopted the following resolution: 1. That whereas the AMERICAN MEDICAL ASSOCIATION sustains no such relationship to publishing houses or boards of education as would enable it to bring such text-books under the supervision of any Committee of the Association, and therefore it is powerless to create a Committee that could do this work as contemplated by the resolution mentioned. And, 2, That the work contemplated by the resolution would involve much time and labor and the selection of men peculiarly fitted to perform the task in a credible and satisfactory manner, whose services could not be secured without adequate compensation, for which there is no provision. Your Committee, therefore, declare the purpose of this resolution to be both without the province of the AMERICAN MEDICAL ASSOCIATION and unpractical.

Association voted to concur.

7. *Dr. Hare's resolution of amity.*—While the Business Committee is in full sympathy with and endorses the idea conveyed in the proposed resolution, it feels that it involves questions which do not properly come within the province of the Committee to decide, but belong to the Association at large. It would, therefore, refer back the resolutions to the Association, with the accompanying proof that identical resolutions were passed by a very large majority at the Baltimore meeting, but before the vote could be announced the matter was laid over for a year, as involving a change in the Constitution. Although notice was then given that it would be brought up the following year, as an amendment to the Constitution and By-laws, such notice was for some reason omitted from the printed program, and so the matter was not brought up.

Affidavit of Mr. Wm. Whitford, official stenographic reporter: "A resolution identical with that offered by Dr. Hare this morning, June 8, was passed at the Baltimore meeting. Before the vote could be announced the matter was laid over for a year, as involving a change in the Constitution."

WHEREAS, In times past circumstances have occurred which have deprived the Association of the presence and co-operation of many members of the profession of high standing, who have contributed much to the advance of medicine and surgery; therefore, be it

Resolved, That this Association invites the New York State Medical Society, the New York County Medical Society, the New York Academy of Medicine and other societies of good and regular standing to send delegates to this Association, who will be received and accredited upon proper credentials from the officers of such societies; and,

Resolved, That all acts or ordinances contrary in spirit or letter are hereby rescinded.

The President—Can the Secretary inform us whether the minutes of the Association will show any of these facts?

The Secretary—I have not the minutes of the previous meetings of the Association with me.

Dr. H. A. Hare of Philadelphia—Mr. President, I have been asked why I offered the resolutions, and—

The President—As soon as a motion is made to receive the report, the Association will hear you, Dr. Hare.

Dr. Hare—I move, Mr. President, that the report of the Business Committee on the resolutions offered by me be received, as this has to be done before the Association votes on it. Seconded.

Dr. W. P. Munn of Denver—I rise to a point of order.

The President—Please state your point of order.

Dr. Munn—Any resolution or resolutions involving questions of ethics, according to our Constitution, must be referred to the Judicial Council. It was an error in the first place to have referred these resolutions to the Business Committee, and they should now be referred to the Judicial Council.

The motion of Dr. Hare was put and carried.

The President—The Association will do Dr. Hare the courtesy of listening to his explanation in regard to this matter.

Dr. Hare—Mr. President, I have been asked why I offered those resolutions yesterday, and with the permission of the Association I would like to explain the reasons therefor. It is unknown to many members of the Association that at the present time there exists in New York State two sets of medical bodies, two State medical societies, two county medical societies, one of the State and one of the county medical societies have a right in this Association by the rules of this body, and they possess that right at the present time by inheritance or heredity. The other county society, a much younger organization, but nevertheless a much more powerful one, both in numbers and in the large amount of scientific work which is contributed each year, has not been admitted to this Association. It is a fact that these two organizations have not adopted in their constitution and by-laws a rigid code of ethics to govern the entire body and which brings each individual member under the care of their censors. Each member in these societies is supposed to do what he believes is right, and not what he believes is wrong. This association, the Society of the County of New York, numbers about thirteen hundred members, while the New York County Association numbers about nine hundred members. It is with the object of admitting, under certain restrictions, the thirteen hundred members of the County Society to our meetings that my resolution was offered. I would not counsel for one moment that that those who consult with irregular practitioners should be admitted to this body with equal rights with ourselves. I desire that every man who comes from the New York County Society or the New York State Medical Society shall sign our code of ethics (applause), and, sir, in the resolutions you will notice that the Judicial Council is empowered to state what society shall come in, so there is no danger of this Association being snowed under by irregular societies or by irregular practitioners. It is simply my wish that the members of this prominent and scientific society, men who are prominent because of their scientific ability, who may not agree on minor points regarding the code of ethics, should have the privileges of the AMERICAN MEDICAL ASSOCIATION.

We have heard a great deal within the last few days about a united country and a united profession. Only a night or two ago the Toastmaster at the joint dinner proposed the toast, "Is There a North? Is There a South?" And our honored President, whom we have elected today, rose to his feet and in the words which all Kentuckians say so well told us there was no North and there was no South; that the different sections of this country were welded together. Is this AMERICAN MEDICAL ASSOCIATION, composed of scientific and enlightened men, going to keep up its petty quarrels because of the societies I have mentioned? There is no North, there is no South, and there is but one AMERICAN MEDICAL ASSOCIATION; there is but one medical profession in America, and there is no irregular medical profession in this country. It is for these reasons that I offered the resolutions yesterday.

I now move, Mr. President, the previous question, and I ask that the roll be called and the ayes and nays be recorded on the previous question and the original resolution, and I would remind the convention that only delegates can vote.

Dr. X. C. Scott of Cleveland, Ohio—I desire, gentlemen, to reply to the speech of Dr. Hare and set forth the facts, as well as the true history of this matter.

The President—In a spirit of fairness, in order to have this matter settled (and I understood Dr. Hare to say that he

wanted the matter settled), I extended him the courtesy of the floor, and now he moves the previous question. Is this letting the matter come before the Association in the proper way? I would not have heard Dr. Hare on this question did I not expect a fair and full statement of the other side of the case, because the point of order raised by Dr. Munn was well taken. I will ask Dr. Hare whether he insists upon the previous question.

Dr. Hare—In view of what you have said, Mr. President, I desire temporarily to withdraw my motion until Dr. Scott has been heard.

Dr. E. D. Ferguson of Troy, N. Y.—A word or two on this subject, Mr. President. The point is this: Dr. Hare has succeeded in presenting one side of the case. I am from the State of New York. I am Secretary of the New York State Medical Association, and before this question is closed I would like an opportunity to say a few words after Dr. Scott has spoken.

Dr. Scott—There is a history connected with this question. The New York State Medical Society is not a young society. It was formerly a constituent of this body; it sent its delegates to this body. But in 1881 it passed a resolution to consult with whom they pleased and decided that it would have no code. In 1882, at our meeting in St. Paul, its delegates presented themselves, but were refused admission by the Judicial Council. The matter then remained quiet until 1891, when some members of the New York State Medical Society came back and were admitted to membership on proper qualifications. And finally this matter was raised in Washington in 1891. In 1892 it was decided by the Judicial Council that they could not be admitted, but, upon the representations of the members of the New York State Medical Society who were present at the Detroit meeting, a committee was appointed by this Association to confer with a committee from the New York State Medical Society to see whether this matter could not be brought about. Now, what was the result of that commission we sent out? We were simply informed that a union could be brought about only by acceding to the terms of the former, and this action was reported at Milwaukee. This Association then passed a resolution to the effect that it would never consider this question in any other light. This matter does not come from the New York State Medical Society asking for admission upon proper qualifications, but from gentlemen entirely outside of that Society. I think it is time for us to consider a request when they present it, and any other plan would result in stultifying and making ourselves the laughing-stock of all communities. (Applause.)

Dr. I. N. Love of St. Louis—I desire simply to present this thought. I have studied the question carefully from the various standpoints, and I am satisfied that this Association desires to keep Dr. Scott in the Judicial Council. I am glad he is there, because he is the watch dog of this body. If I interpret the resolutions of Dr. Hare rightly, they permit many able and scientific men of the profession in New York County to enter this Association. They were in the minority, and they could do nothing, as their hands were tied. These resolutions of Dr. Hare permit them to enter this Association on the same terms individually as we do. Dr. Scott has made the point that members of the State and county societies have presented no request, and that it has been done by outside parties. How can they, in the name of heaven, when they can not get in here? (Laughter.) I think, Mr. Chairman, if the point is made that these gentlemen can individually join the Association by signing its rules and regulations and code of ethics the same as the rest of us do as individuals, I certainly would favor the suggestion of Dr. Hare.

Dr. C. Lester Hall of Kansas City, Mo.—I would like to ask if this is a delegated body?

The President—Yes, sir.

Dr. E. D. Ferguson—I will endeavor to be brief in my remarks, for Dr. Scott has practically covered this field. He has been accurate with the exception of two or three dates which are immaterial as to the essential question under discussion. I wish to state, however, a few things familiar to many of the delegates on the floor, but unfortunately are not familiar to a majority of the delegates and to the majority of the profession throughout the country. This is a very tender and very serious question. We of the New York State Medical Association, entitled to representation here, regret as much as Dr. Hare or any member of the profession in this country that all of the members of the medical profession in the State of New York are not entitled to representation in this body. But, Mr. Chairman, it is their own fault. They deliberately—and I will not go into a detailed history at this time—cut themselves off from this Association, and they were told by such action they were cutting themselves off. They said, "we do not care; the AMERICAN MEDICAL ASSOCIATION is only

a junketing affair and we are the scientific medical association of the State of New York; we do not want anything to do with them; they will come to us bye and bye." The AMERICAN MEDICAL ASSOCIATION, Mr. Chairman, was not as large an organization then as it is today. This was fifteen years ago. But the AMERICAN MEDICAL ASSOCIATION has grown, and it is now desirable for these men to come into the Association and participate in the transactions of this body and to read papers. As the Secretary of the New York State Medical Association since its organization, I have been cognizant of the wishes of men to do this thing, and I have been repeatedly asked if there was not some way by which these men would be entitled to the privileges of this floor. They have not as a body given at any time any sign that they wished to come back into full fellowship with this Association. The AMERICAN MEDICAL ASSOCIATION, under the Presidency of Dr. Marcy, appointed a committee to meet with a committee from the New York State Medical Society and a committee from the New York State Medical Association to see if this matter could not be arranged. The New York State Medical Society said it had no occasion to appoint any committee; yet in the face of all these facts the New York State Medical Society, the elder organization not the younger, one of the pioneer bodies, in fact the pioneer body in the organization of the AMERICAN MEDICAL ASSOCIATION, for Dr. N. S. Davis was then a member of the New York State Medical Society, in spite of these facts, they have rejected, in every possible way they could do officially, efforts to reinstate themselves in the AMERICAN MEDICAL ASSOCIATION. Now, we have here resolutions inviting these bodies to send delegates. These gentlemen are said to come here pure and holy because they can subscribe to our Code of Ethics. If they can do this the door is open for them, for they can join their local organizations in New York and come here as delegates. (Applause.) No worthy man will be refused membership in the organization who is entitled to representation here. We are not here fighting for our existence and against bodies entitled to representation in this Association. We feel that every member of the AMERICAN MEDICAL ASSOCIATION should stand by us, because at the expense of a good deal of time and labor and a great deal of trouble and mental affliction, we have stood by what we believed to be the cardinal principles of the organization of the AMERICAN MEDICAL ASSOCIATION. (Applause.)

Mr. Chairman, now, they say, these men can come here and be received as delegates. Delegates from what? Delegates from a body which has spat contumely upon us and has never withdrawn it. Are we to ask and beg the New York State Medical Society to come back into the fold of the AMERICAN MEDICAL ASSOCIATION? (Cries of "No! No!") Was there anything in any part of the Code of Ethics that put them out? No. It was their own voluntary act. It is absurd that an organization like this should ask men to become fellows who have by every official act they have committed said they wanted no fellowship with us. (Applause.)

Dr. W. P. Munn of Denver—Mr. Chairman and members of the Association, Colorado desires to take a little time outside of its entertainment to say a few words upon these resolutions. The resolutions offered by Dr. Hobart A. Hare of Philadelphia are the inoculated scalpel by which it is proposed to introduce the sepsis of commercialism into the AMERICAN MEDICAL ASSOCIATION. (Cheers and cries of "Good! Good!") (Here Dr. Hare interrupted the speaker and was informed by the President that Dr. Munn had the floor.)

Dr. Munn (resuming)—I had nothing to say while Dr. Hare held the floor. Dr. Hare is a delegate to this body from Pennsylvania. It is eight years now since I left my home in that State to come to Colorado. I know from many visits among the practitioners of Pennsylvania that today I can voice the sentiments of the profession there more accurately, more faithfully, more truthfully than Dr. Hare can before you today. (Applause.) These are the resolutions of Dr. Hare and they could not carry for one moment before the State Medical Society of Pennsylvania. There are members of the State Medical Society of Pennsylvania here and if I am wrong let the majority of them correct me. In this Western country we have had all we could do to uphold the Code of Ethics of the AMERICAN MEDICAL ASSOCIATION, but we have done it. We have had all we could do to keep out the dead rot of commercialism, and are we going to be trodden down by this derelict, dead, rotten society of New York which is continually sending—(Cries of "No!" mingled with hisses, the final words of the sentence being inaudible.)

Dr. Jackson of Philadelphia—I came here as a delegate from Philadelphia. I sincerely hope that this question will be decided once and for all. Let us understand what the question is. The question is, Shall the AMERICAN MEDICAL ASSOCIATION be a representative body, representative of the local

organizations of the profession throughout the country, or shall it consist of individual members attracted to the meeting who represent themselves? This is the question we have to decide, and I hope it will be decided now once and for all.

Dr. Hare—I simply wish to say, Mr. President, that I had no intention of making erroneous statements, if I did make them. In withdrawing my previous question temporarily, I did so as a matter of courtesy. I tried in my remarks to use no language which would be offensive to either side of the question; but I regret, sir, that language has since been used which I think is offensive. I want to say to this Association, that I am the last man in my State to do what has been referred to by Dr. Munn. We have in New York State a large body of practitioners who want to come back to this Association. Let them come to us; let them sign the Code of Ethics, and the thing which has been referred to with strong adjectives will have the life sapped out of it.

Dr. W. T. Bishop of Harrisburg, Pa.—Mr. President; I rise to a point of order.

The President—Please state it.

Dr. Bishop—If the resolution introduced by Dr. Hare is passed it will contravene the organic law of our Association. If we desire to admit these men, we must change the organic law so that we can admit them. But do not let us admit them and override the law. The organic law of this Association provides that of the several State and several county societies, there shall be but one State and one county society in each State and in each county. Now, then, because it does contravene the law the resolution is out of order, and there is no necessity of introducing these personal reflections. There is no necessity of introducing misstatements. I make the point of order, then, that this matter is in contravention to the organic law of the Association, and the whole matter is out of order.

(The Chair sustained the point of order amid laughter and applause.)

8. *Dr. Keen's resolution for the dissemination of scientific knowledge.*—After discussion this was recommended as follows: Your Committee, to whom was referred the resolution of Dr. Keen, relative to the appointment of a co-operative committee of five who should consider the desirability of formulating plans concerning experimental research, would respectfully report that inasmuch as the province of such committee is but to consider the desirability of formulating plans for such a purpose, we would, therefore, endorse the resolution and recommend the appointment of such a committee. Adopted.

9. *Dr. Gould's resolution as to medical libraries.*—After discussion these were recommended for adoption by the Association. Adopted.

10. The invitation from the Mayor of Chicago and others to hold the next meeting of the Association in that city, was referred to the Nominating Committee.

11. *Dr. Bailey's resolution in regard to the appointment of a new general secretary.*—After a full discussion it was decided that it was infeasible to attempt to put it in operation this year, and the following report of the same was sent to the Association: "While the Committee fully agree as to the desirability of having much more active secretary work done for the Association, and believe that the plan proposed would greatly increase the scope and usefulness of the Association, it is not prepared at the moment to recommend the adoption of the resolution. It is a matter of such very great importance that further consideration of the details involved is necessary, and as it may possibly involve a change in the Constitution and By-Laws, your Committee has decided to recommend that the matter lie over for one year, and hereby gives notice that it proposes such changes, if any are necessary, in the Constitution and By-Laws at the next annual meeting of the Association."

Dr. William Bailey of Louisville—This resolution came to me as representing the majority of the Business Committee. It was the wish of the Committee that I present this resolution in the interests of the Association from the floor. I wish to state before the Association that I was not actuated by any antagonism to our worthy Secretary, Dr. Atkinson. This is all I desire to say.

Dr. I. N. Love—Inasmuch as this pertains to the expenditure of money, I move that it be referred to the Board of Trustees. Carried.

Report as amended was accepted.

12. *Dr. Stone's communication in regard to a permanent badge for membership in the Association.*—Dr. Stone appeared before the Committee exhibiting the badge and a drawing of them, and explaining the desirability of the same. After discussion the following was adopted: "The Committee report in regard to the proposal of Dr. Stone in regard to a permanent

badge or button for members of the AMERICAN MEDICAL ASSOCIATION, that in their opinion such a badge, or any badge, for permanent use, would neither add to the dignity of the individual members nor increase the efficiency of the Association and would, therefore, recommend that Dr. Stone's proposal be not accepted."

Dr. D. S. Reynolds—I move to amend the report of the Business Committee to this effect:

Resolved, That the proposed official button presented by Dr. French Stone of Indiana be and it is hereby accepted and adopted as the permanent badge of the Association. Seconded.

Dr. L. Connor—I think the Code of Ethics prohibits dealing in patent instruments.

Dr. I. N. Love—It is desirable that we should have a permanent button that we can wear the year round. This button, as I understand it, is from the best men of Indiana and Kentucky and has been carefully considered by them. It is a beautiful and attractive button, and I think would settle the question favorably and it would then be available for all of us. It would go with our credentials, and I therefore would like to see it adopted.

The President—The point of order made by Dr. Connor is not well taken.

Dr. G. C. Savage—I do not think any action this Association can take would give more dignity or would tend to increase the membership more largely than the amendment offered by Dr. Reynolds. As a member of the Association, I would feel proud to wear this button.

The amendment of Dr. Reynolds was adopted.

13. *The communication from the Ohio State Medical Association in regard to a special committee on National Legislation.*—After discussion the Committee adopted the following recommendation to the Association: "The Committee would report that it does not see its way clear to the efficient working of such a Committee on National Legislation without considerable expenditure of the funds of the Association, and does not therefore recommend the appointment of such a Committee." The Association concurred in the report.

14. *Dr. Horner's plan for a Medical Relief Association.*—The Committee would report that the same matter was referred to them last year, and that they reported as follows: "The recommendation and resolutions were referred back to Dr. Horner as impracticable at the present time, but with the approval of the Committee as to the general plan." After further extended consideration of the subject your Committee do not see their way clear to recommending the adoption of the plan. Adopted.

Dr. Gihon moved that this action be reconsidered. Carried.

Dr. Gihon then moved that the matter be laid on the table. Carried.

Dr. Sanders asked what disposition had been made of the resolutions offered by him at a previous session. He said that it was desirable that the report be made early. He would like to have the voice of the Committee expressed as early as possible.

On motion of Dr. D. S. Reynolds, the resolutions were referred to the Business Committee with power to act.

Dr. J. B. Murphy of Chicago then delivered the Oration on Surgery. He selected for his subject, "Surgery of the Lung."

On motion, Dr. Murphy was extended a vote of thanks for his able and instructive address, after which the Association adjourned until 11 A.M. Friday.

(To be concluded.)

BOOK NOTICES.

Clinical Lectures on Diseases of the Heart and Aorta. By GEORGE WILLIAM BALFOUR, M.D., LL.D., F.R.C.P., F.R.S. Third Edition, pp. 479, 8vo, cloth. Edinburgh: Adam & Charles Black, 1898; A. C. McClurg & Co., Chicago.

Mr. Balfour has been so long and favorably known in this country as an author on diseases of circulation, especially for his observation and treatment of aneurysm and cardiac diseases that he needs no introduction in America. We may say, however, that this volume, the first edition of which was issued in 1875, has been entirely revised and rewritten and considerable new matter has been incorporated and there is no question but the new edition will be as favorably received as its predecessors.

International Clinics. A Quarterly of Clinical Lectures. Edited by JUDSON DALAND, M.D., Philadelphia; J. MITCHELL BRUCE, M.D., F.R.C.P. London; DAVID W. FINLAY, M.D., F.R.

C. P. Scotland, pp. 355. Philadelphia: J. B. Lippincott Company, 1898.

The records of cases can never become stale or useless even though the remarks made upon them at the time may become obsolete by the changes of time; for that reason the case records embodied in these series will always be useful and instructive and may be referred to years after the date of their publication.

For the practitioner who desires to keep pace with the existing practice of the times in all branches and be in touch with the current fads and improvements of medicine and surgery, he can accomplish his purpose in no better way than by the careful perusal of the volumes of this series.

Outlines of Practical Hygiene. By C. GILMAN CURRIER, M.D. Third Edition, revised and enlarged, 8vo, cloth, pp. 482. New York: E. B. Treat & Co., 1898.

This revised and enlarged edition incorporates the essentials of sanitary science of practical hygiene. It is largely used as a text book. This work is extremely well written and of great value to the sanitarian, civil engineer and practicing physician.

Report on Bubonic Plague. Being a report based upon observation on 939 cases of Bubonic Plague, treated at the Municipal Hospital for infectious diseases at Arthur Road, Bombay, from September 24, 1896, to February 28, 1897, by KHAN BAHADUR N. H. CHOSKY, Extra Assistant Health Officer Bombay Municipality, Bombay, printed at the "Times of India" Steam Press, 1897.

This contains the most complete report of the cases during the late Bubonic epidemic at Bombay that has appeared. Fifty-four autopsies were made of the cases, 47 by the members of the Austrian Plague Commission and the remainder by the hospital staff. Nearly one-half of the bound volume is occupied by clinical charts.

We referred to this in our editorial on p. 29 of the current volume.

Illustrated Skin Diseases. An Atlas and Text with special reference to Modern Diagnosis and the most Approved Methods of Treatment, by WILLIAM S. GOTTHEIL, M.D.

This work, three portfolios of which have been issued, will be issued in quarter portfolios, each containing 24 quarto papers, a text with numerous formulæ and four plates of cases from life, by a new photographic process.

The illustrations are accurate and numerous, and the plates are extremely life-like. We shall look for the succeeding portfolios with interest, and in the meantime compliment the author and the publisher on the splendid series so far presented.

The Purification of Public Water Supplies. By JOHN W. HILL, Consulting Engineer, etc., etc., 8vo., cl., pp. 304. New York: D. Van Nostrand Co., 1898.

This work is a continuation of a series of lectures and papers on the quality of public water supplies which the author has read before several scientific societies and in universities during the past five years, and presents briefly:

1. The facts and causes of pollution of sources of public water supplies.
2. The effect of this pollution on the typhoid fever rates of our larger cities.
3. Illustrates by few examples how typhoid rates have been reduced by the introduction of water from purer natural sources and by filtration of polluted water.

Data are given on the methods of construction and operation of sand filters with the cost of filter construction. In these days when health officers and sanitarians generally are deeply impressed with the importance and necessity of vigorous attack on the water pollution and the prevention of diseases arising from bad water, this work will be found of great value. The book is thorough and complete and may be depended upon by Health Officers generally and others interested, as presenting the latest established views on the subject.

MISCELLANY.

Boasting of No Use.—We observe with a great deal of pain, almost amounting to sorrow, that our great and good friend, the *Medical Record*, one of Wm. Wood and Company's publications, is inclined to amuse itself by the publication of incomplete and incorrect reports of the last annual meeting in advance of the other medical journals, and particularly in advance of the report by the *JOURNAL*. The *JOURNAL* in printing the reports of the Transactions of the Association must have them officially correct, consequently it can not take them from any person but the proper officers of the Association. If the example of the *Record* were followed, it would be quite easy to fill the *JOURNAL* with pages of half-edited and incorrect matter, largely taken from the lay press at the place of meeting. Reference to this subject was made necessary by the Paracelsian bombast of the *Record*, whose Spanish-like tendency to mislead its unfortunate constituents is matter for sincere regret.

THE RECENT MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

It is so well known that the *Medical Record* is always ahead of its contemporaries in printing the medical news of the day and reports of important meetings throughout the world, that it seems almost superfluous to remind our readers again of its pre-eminence in this respect. The report of the Denver meeting of the AMERICAN MEDICAL ASSOCIATION was given to our subscribers complete two weeks ago. Some other journals are still stringing it along in their columns, and it is almost pathetic to read the apology of the official journal of the Association in its issue of June 25th, for its neglect promptly to print the proceedings, even of the general sessions. —*Medical Record*, July 2.

Bacterial Pathogenesis of Biliary Lithiasis. The *Presse Méd.* of May 21 contains a study of this subject describing experimental lithiasis produced by biliary infections, and the microbes found in human calculi. They are always the bacillus coli or Eberth's bacillus, the calculi result from a catarrhal and desquamating angiocholecystitis which they set up. The conditions that favor the ascension of the bacilli into the biliary passages are mechanical or due to alterations in the secretions, or both. These factors may be inherited, imparting a predisposition to infection, possibly favored by some congenital special disposition of the biliary passages.

Liver Abscess Due to Ascaris Lumbricoides.—Another case is reported from the Greifswald clinic, making the nineteenth on record. When the abscess was evacuated a lively worm was found in the contents. The extreme tension of the abscess seems to prove that the worm could not have entered it secondarily, as the contents would have been forced out through any hole large enough to admit it. As it primarily found its way into the liver it probably carried infectious germs with it which set up the abscess. —*Deutsche Med. Woch.*, May 19.

Cancer of the Thoracic Duct.—Troisier has observed three cases in which a cancer of the uterus, stomach or suprarenal was accompanied by inflammatory proliferation and cancerous vegetation nearly the whole length of the thoracic duct. Only one other case is on record (Weigert's). A left supraclavicular adenopathy was present in each case, to which he has already called attention as valuable in the diagnosis of cancers of the abdomen. The occlusion of the thoracic duct was not accompanied by any retention of chyle in the intestinal lymphatics, showing that the lymph must be carried over some collateral route. —*Presse Méd.*, May 21.

Official Advice for the Soldiers in Cuba.—Before embarking for Cuba, Lieut. Col. Benjamin F. Pope, Chief Surgeon of the Fifth Army Corps, General Shafter commanding, issued a memorandum of instructions to the troops, with the view of protecting them from insanitary influences during the service before them in the Island of Cuba:

The Chief Surgeon issues the following memorandum of instructions to the soldiers of this command for the preserva-

tion of their health in the tropics: The body adapts itself readily to changes of climate. You do not require any special preparation for the climate of Cuba. You should meet the heat in the same way that you do in the summer season in the North. Avoid, therefore, the use of medicines that are recommended to protect the body against the action of climate. The danger in the tropics does not come from the direct action of the climate. The danger is due to the presence in some districts of the warm country of the microbes of certain diseases. There are no medicines that will protect us from these diseases. The chief measures for their prevention will be instituted by your commanding officer. Do not take quinin regularly when your health is good. Do not take purgatives when the bowels are regular. Drink boiled water when you can not get natural spring water. Stagnant surface water is specially dangerous. If possible drink water only at meal time. The fruits of the country are wholesome when eaten in season. Avoid unripe and unsound fruits. Peel all fruits before eating. Use as little alcoholic beverages as possible. The clothing should be light and loose. When wet from rain or sweat remove it for drying, and rub the body briskly with a towel. Bathe in running streams, once a day if possible. Keep the body clean. If exposed to draughts when perspiring freely put on some extra covers. Sleep with dry clothes. The health of the Command will depend, to a great extent, upon the strict observance of orders not to communicate with suspected people or places. All sickness should be reported at once to a medical officer.

Beware of the Manchineal Tree. The following circular, prepared by Dr. J. T. Rothrock, Commissioner of Forestry, Department of Agriculture of the Commonwealth of Pennsylvania, has been published and distributed by direction of Hon. Daniel H. Hastings, Governor of the Commonwealth:

Branch and fruit of Manchineal tree.

SOLDIERS!

BEWARE OF THE MANCHINEAL TREE!!

It grows along the sea shore in Cuba, and the West India Islands generally.

It is from forty to fifty feet high, has oval, pointed, toothed, shining leaves, which are from three to four inches long.

When the fresh leaves are pulled off a drop of milky juice comes from the leaf stem.

The fruit is a yellowish green, fragrant, and somewhat resembles an apple in shape.

If bitten into it makes the mouth very sore for a time and may produce serious results.

After handling any part of the tree—root, leaves or fruit—rubbing the eyes may cause them to become seriously inflamed.

Mucous membranes (such as the red margin of the lips or eyes, or anus) are particularly subject to its poisonous effect.

It is said by many of the natives to cause poisonous effects even if the tree is not touched, but by simply being in its neighborhood.

Many persons are alleged to have been injured from being under the tree during a shower, when the drops of water fell upon them from the tree.

Some persons are more sensitive to the effect of this poison than others. In fact there are a few who are not affected by it at all, just as is the case with our poison oak or poison ivy, the chief difference being that the manchineal affects the mucous membranes, above alluded to, more than the skin proper, whereas the poison ivy affects the skin much more frequently than it does the mucous membranes.

Many persons of experience in the tropics assert that it is unwise to camp near this tree.

If poisoned by the manchineal, and beyond reach of your surgeon's help, the best thing to do is to wash the part affected freely with salt water.

It is sometimes called by the natives manzanilla (pronounced man-za-ne-ya).

Local Anesthesia in Operation.—In the *Annals of Surgery* for May, Lillenthal of New York reports observations made on the effect of cocain, eucain and nitrous oxid in the performance of operations rarely done without ether or chloroform narcosis, during the last three years. He considers eucain the best local anesthetic. Compared with cocain, solutions of greater strength are required, but eucain is far less poisonous and stronger solutions may be safely employed. He generally uses from 6 to 10 per cent. solutions and in over fifty cases has not noted a single instance of toxic symptoms. He finds that injection of five grains of the hydrochlorate in one sitting is usually sufficient for an operation of considerable magnitude, e. g., herniotomy, but he has used as much as nine grains. He finds the benumbing power of eucain is quite as certain as of cocain and has never seen prostration with cardiac failure which often follows cocain in smaller doses. Eucain has a very persistent effect and on the mucous membranes does not act quite so effectively as cocain on mere contact. On this account, in operations on tissues covered by mucous membrane, he usually applies a little cocain solution first and then injects the eucain. If the operation is to be a severe one, or prolonged, he gives the patient a small dose of morphin a quarter of an hour before, for the effect on the mind. He usually promises the patient to employ general narcosis if the patient finds that he is unable to bear the pain, but in no case has it been necessary so to do. While the skin is perfectly anesthetized, the tissues beneath it are not and section of muscle causes a dull pain not hard to bear, but section of tendon is not felt. In some operations the absence of the unconsciousness accompanying general narcosis makes the work easier, as in herniotomy where the rupture is small and easily reducible. The patient under local anesthetics can bring down the hernia by coughing or voluntary straining, while in general narcosis the surgeon would be obliged to wait for vomiting or some other reflex strain. Again, in tendon suture, voluntary motion supplies at once the physiologic test as to whether the ends have been correctly adjusted. He believes that in such operations as castration, colotomy, herniotomy by the Bassini and similar methods, cholecystotomy, drainage of empyema of the thorax, etc., local anesthetics should be first choice.

European Appetite for Drink.—Henry W. Fisher in the *New York Sunday Magazine*, June 12, states that each Dane, in the average, swallows twenty-seven quarts of strong liquor yearly. But the Swedes are contented with five quarts of alcohol, twelve quarts of beer and 0.4 quarts of wine each, every year. Each German, taking them all in all and without reference to the different races, consumes 117 quarts of beer, nearly six quarts of wine and a little over thirteen quarts of alcohol, or strong liquors, every year. But the French, at least, are a "sober people." Frenchmen drink but little beer,

only twenty-three quarts in the rural districts and but eleven quarts in Paris for each person per annum. But they each swallow 105 quarts of wine yearly. In the matter of strong liquors, they require twelve and three-fourths quarts each per annum, that is, they think they do and live up to that erroneous conviction. Austria-Hungary is generally rated as a wine-drinking country, but is better than its reputation in one respect at least. The Austrians and Hungarians each drink twenty-two quarts of wine a year; to this they add forty-four quarts of beer and the same quantity of strong liquors as the Frenchman. England's consumption of liquors allows 145 quarts of beer, 1.8 quarts of wine and 8.5 quarts of liquor to each man per annum. The Belgians are tremendous beer drinkers. One hundred and seventy quarts is the average quantity consumed in Leopold's kingdom; but even then they are only boys compared with the festive Bavarian. The Bavarians each swallow on an average 237 quarts of beer every year. In Munich each man, woman and child consumes 570 quarts of beer per annum. The Frankforters wash down their Frankfurters with 430 quarts of beer each a year. The citizens of Nuremberg come next with 322 quarts, the Berliners follow with 160 quarts, the Viennese with 145 quarts, the men, women and children of Moscow with twenty-eight quarts.

Societies.

The following recent meetings are noted:

California.—Fresno County Medical Society, Fresno, June 7.

Connecticut. Waterbury Medical Association, Waterbury, June 6.

Delaware.—State Medical Society, Wilmington, June 14.

Florida.—Duval County Medical Association, Jacksonville, June 7.

Illinois.—Rock River Valley Medical Association, Sterling, June 9; Vermilion County Medical Association, Danville, June 14.

Iowa.—Des Moines Valley Medical Association, Ottumwa, June 23; Iowa Central Medical Society, Marshalltown, June 15; Polk County Medical Society, Des Moines, June 7.

Massachusetts.—State Medical Society, Boston.

Michigan.—Calhoun County Medical Association, Marshall, June 7; Saginaw County Medical Association, Saginaw, June 10.

Minnesota. Hennepin County Medical Society, Minneapolis, June 6.

New Hampshire.—Dover Medical Society, Dover, June 1; Manchester Medical Association, June 9.

New Jersey.—New Jersey Surgical Society, Newark, June 7; Warren County Medical Society, Belvidere, June 7.

New Mexico.—New Mexico Medical Society, Las Vegas, June 4.

New York.—Erie County Medical Society, Buffalo, June 14; Hornellsville Medical and Surgical Association, June 7; Syracuse Academy of Medicine, June 14.

Pennsylvania.—Easton Medical Society, June 9; Lebanon County Medical Society, Lebanon, June 11.

Texas.—Kaufman County Medical Society, Kaufman, June 6.

Wisconsin.—Kenosha County Medical Society, Kenosha, June 3; Rock County Medical Society, Janesville, June 3.

Philadelphia.

WAR REVENUE TAX.—It was rather strange that charitable institutions such as hospitals should be made to pay a part of the cost of war with Spain, but they are affected in the clause of the bill relating to inheritances and legacies, which provides that a tax of \$5 on the \$100 be applied to all legacies, exceeding the sum of \$10,000. Philadelphia has always been known far and wide for its generosity toward its charitable institutions, but if the predictions of Provost Harrison of the University of Pennsylvania come true, some of that revenue may be diverted to other channels. In a recent interview he expressed himself as follows: "Hereafter we will have to pay 10 per cent. on our larger legacies, \$10,000 on every \$100,000 bequest we receive, for the State already taxes us 5 per cent. in addition. For example, a bequest we have recently received from Mrs. John Field, of \$50,000, would have been reduced \$5,000 if this new law had been operative when the bequest was

received. Such a heavy tax will have the effect of driving away large bequests. It will have a very deterrent influence upon people disposed to leave in their wills large sums for charitable purposes and it is a most unwise measure." How its baneful influence will be felt can be shown by reference to legacies left to two hospitals of this city. For instance, the Pennsylvania Hospital, one of the oldest charitable institutions in the United States, since 1894 has received bequests to the amount of \$110,000 and under the regulation of the new war measure over \$10,000 would have to be paid back into the lap of the United States. Should it not be disappointed there will be at least \$300,000 left to that institution during the current year. The hospital of the University of Pennsylvania will also have some of its revenue cut off. It is shown by proper reports that this hospital since 1893 has received bequests aggregating \$172,682.67, and in two years would have been forced to pay \$11,000 to the government to support this war. It does seem that at least the charitable institutions might have been left untaxed.

NORDAU OR LOMBROSO MIGHT STUDY A PENNSYLVANIA PROFESSOR.—Those physicians of Philadelphia and the people at large who are acquainted with the recent acts of Prof. George H. Stephens are astounded with the awful impulse which prompted him to destroy by fire the idol of Lafayette College, Pardee Hall. Educated for the ministry by the subscription of a church, it was thought that his course in Princeton College would render to the world and to them a man of great attainments. According to report, however, he forgot his benefactors and accepted a position at Lafayette College as Adjunct Professor of Moral Philosophy. After a residence there of about three years it is reported that his place was declared vacant, and he is quoted as saying that some insane impulse carried him onward to take revenge upon that institution, beginning first by acts of vandalism, such as damaging the chapel organ, hiding the hymn books and finally culminating in the graver crime of burning Pardee Hall.

IMPORTANT FACTOR IN A TRIAL.—Peter E. Smith, a member of the Select Council, stands charged by Walter N. Stevenson, a member of the Common Council, with offering a bribe to the latter member, to control his influence in voting against the celebrated "Loan Bill," with which readers of the JOURNAL are already familiar. Smith, however, seems to have been born under a lucky star, for although the case has been called a number of times it has as often been continued. When the day came for the trial Smith's family physician, Dr. William Stiles, gave it as his opinion that the former's physical condition would not permit him to be tried at this time, as he was suffering from gout, heart and kidney trouble. Judge Penny-packer granted a continuance.

DEATHS IN PHILADELPHIA.—For the week ending June 25 there have been reported to the Board of Health 387 deaths. Of these 152 have been in children under 5 years of age. This is a decrease of 112 over the previous week and 41 less than for the same period of last year. The causes of death were: Consumption, 34; cholera infantum, 34; inflammation of brain, 25; inflammation of stomach and bowels, 20; heart disease, 20; inflammation of lungs, 18; old age, 14; marasmus, 13; nephritis, 14; convulsions, 11. In addition, for the same period, there were 63 cases of diphtheria, 23 of scarlet fever and 91 of typhoid fever, from all of which there were 20 deaths.

HOT DAY.—June 25 was marked as one of the hot days in Philadelphia. At 5 A.M. the temperature was as low as 68 degrees, but at 8 A.M. had risen to 75 degrees, the humidity at that time being 78 degrees, making the air stifling. Later in the day the mercury gradually rose until the temperature was 94 degrees about 4 P.M. The excessive heat and humidity combined produced twelve prostrations during the twenty-four hours.

THE PUBLIC SERVICE.

Army Changes. Official List of Changes in the Stations and duties of officers serving in the Medical Department, U. S. Army, from June 25 to July 1, 1898.

Acting Asst. Surgeon Eugene H. Hartnett, U. S. A., ordered from Washington, D. C., to duty in U. S. general hospital, Ft. Monroe, Va.
Acting Asst. Surgeon Henry S. Greenleaf, U. S. A., ordered to report in person to the Major General commanding the Army for duty.
Acting Asst. Surgeon S. Melville Waterhouse, U. S. A., at general hospital, Ft. Myer, Va., ordered to accompany artillery battalion from Washington Bks., D. C., to San Francisco, Cal.
Acting Asst. Surgeon Thomas A. Smith, U. S. A., is relieved from duty on U. S. hospital ship "Relief," New York City, N. Y., and ordered to Ft. Slocum, N. Y., for duty.
First Lieut. Franklin M. Kemp, Asst. Surgeon, to San Francisco, Cal., for duty with expedition to the Philippine Islands.
Acting Asst. Surgeon J. W. Donnelly, U. S. A.; Acting Asst. Surgeon Stephen M. Long, U. S. A., and Acting Asst. Surgeon D. T. Lainé, U. S. A., ordered from Washington, D. C., to Tampa, Fla.
Acting Asst. Surgeon R. Fleming Jones, U. S. A., is relieved from duty at Ft. Bliss, Texas, and ordered to Tampa, Fla.
Capt. Charles E. B. Flagg, Asst. Surgeon, is ordered from Columbus Bks., Ohio, to Ft. McPherson, Ga., for duty in the general hospital.
Major W. Fitzhugh Carter, Surgeon U. S. A., is ordered from Nashville, Tenn., to Tampa, Fla., for duty with Fourth Army Corps.
Acting Asst. Surgeon Edwin P. Hayward, U. S. A., is ordered from Kansas City, Mo., to Leiter general hospital, Chickamauga, Ga.
Acting Asst. Surgeon C. F. de Wey, U. S. A., ordered from Louisville, Ky., to San Francisco, Cal., for duty with Philippine expedition.

CHANGE OF ADDRESS.

Angus, D. A., from 1228 to 1240 Milwaukee Av., Chicago.
Beckman, O. H., from Tyrvis, Finland, to Astoria, Ore.
Bell, J. W., from 1600 Fourth Av. to 2301 S. Bryant, Minneapolis, Minn.
Bellamy, R., from New York, N. Y., to Ocean House, Newport, R. I.
Berry B., from 3400 Morgan to 3142 Loust St., St. Louis, Mo.
Christofferson, A. L., from Lind Center to Oshkosh, Wis.
Clayton, C. F., from 4800 N. Clark to 600 W. 59th St., Chicago.
Cole, F. M., from Ida Grove to Hull, Mich.
Cutter, J. B., from Challes, Idaho, to California Hotel, San Francisco.
Edwards, Mrs. C., from Detroit to Cass City, Mich.
Fisher, G. C., from Ann Arbor, Mich., to 2601 Calumet Av., Chicago.
Hinsdale, G., from Philadelphia, Pa., to Bethlehem, N. H.
Howard, W. E., from Kasbeer to Ohio, Ill.
Hughes, J. D., from Sonneberg to Coburg, Germany.
Johnson, T. T., from Starbuck to Walla Walla, Wash.
Latta, M. J., from Equitable Bldg. to Good Bldg., Des Moines, Iowa.
Love, L. F., from 600 S. 45th St. to 4107 Chester Av., Philadelphia, Pa.
McCassey, J. H., from 126 S. Ludlow to 5th and Wilkinson Sts., Dayton, Ohio.
Malone, L. A., from 119 N. New Jersey St. to 6 Stewart Pl., Indianapolis.
Mason, W. S., from Philadelphia to Williamstown, Pa.
Miles, W., from Chicago to Littleton, Ill.
Moore, J. W., from 1 W. 72d to 45 W. 71st St., New York, N. Y.
Nichols, C. L., from 1923 Wirt St. to Karback Bldg., Omaha, Neb.
Noyes, A. A., from 1205 20 Avenue N. to 1910 Hawthorn Av., Minneapolis.
O'Leary, A. P., from Ann Arbor, Mich., to The Dalles, Ore.
Pampel, B. L., from Wymore to Douglas Co. Hosp., Omaha, Neb.
Riesman, D., from 801 N. 6th to 326 S. 16th St., Philadelphia, Pa.
Rogers, A. S., from Ann Arbor to Vassar, Mich.
Rogers, W. W., from Jones Prairie to Carlton, Texas.
Schick, G., from Chicago to "The Southern Hotel," Chicago.
Sheffield, H. B., from 691 Prospect Av. to 331 E. 50th St., New York.
Shoemaker, S. S., from Reiffsburg, Ind., to Eureka Springs, Ark.
Taylor, P. K., from 211 W. 139th St., New York, to Kingston, R. I.
Toan, J. W., from Portland to Otsego, Mich.
Van der Veen, C., from Ann Arbor to 148 Fountal St., Grand Rapids.
Van Duyen, A. C., from 52 Cottage Grove Av. to 2950 Indiana Av., Chicago.
Wilder, H. R., from Swanton to 25 N. Union St., Burlington, Vt.
Wisman, L. J., from Ann Arbor to Frontier, Mich.
Woodward, J. H., from New York, N. Y., to Burlington, Vt.
Wyland, G. V., from Lyndon Ill., to Marcellus, Mich.

No. 3.

ORIGINAL ARTICLES.

THE DIFFERENTIATION OF THE CARDIAC INCOMPETENCY OF INTRINSIC HEART DISEASE AND OF CHRONIC NEPHRITIS.

Presented to the Section on the Practice of Medicine at the Forty-ninth Annual Meeting of the American Medical Association held at Denver, Colo., June 7-10, 1898.

BY FRANK BILLINGS, M.D.

CHICAGO, ILL.

The recognition of an incompetent heart is usually not difficult. The dyspnea of exertion, the sense of post-sternal weight and constriction of the chest, the cough of exertion, and upon assuming the recumbent position, the enlarged liver with tenderness and often with pain or a feeling of weight in the epigastrium, the indigestion of portal congestion, the usually scant urine, the edema of the feet, or all of the above named conditions much aggravated until constant dyspnea with orthopnea, general anasarca, excessive physical weakness, marked palor, or palor and cyanosis give unmistakable evidence of cardiac weakness. The local signs of valvular disease may be absent or present. Signs of cardiac enlargement with dilatation of the chambers of the heart are present and may usually be recognized.

These phenomena are usually present in varying degrees of severity, in an incompetent heart. When due to intrinsic heart disease a valvular lesion or some other cause of dilatation of the heart and weakness of the heart muscle is present the chronic nephritis, cardio-vascular changes occur, and especially in the form classed as diffuse interstitial nephritis. In the latter stages especially of chronic nephritis the heart may become so dilated that it becomes incompetent, and the symptoms and signs enumerated appear. The urinary findings, the symptoms of uremia and other characteristic signs may plainly indicate the primary nephritis. In many cases, however, the differentiation can not be easily made, and in a few examples the diagnosis may remain in doubt until the side light of the dead house clears up the darkness. It is with these doubtful cases that this brief paper has to deal.

The following case will serve as a text and more clearly illustrate the subject.

Mr. W. McF.; aged 50; American; lawyer; married. Came to me on Sept. 12, 1894, and presented the following history:

Father died at 76 years; mother living, aged 72 years, and in good health. One brother died of acute pneumonitis. The father suffered from a tremulousness of the right arm, and the patient has had from birth a tremulousness of the right upper extremity, which is intensified by the presence of strangers, or by an attempt on the part of the patient to suppress it. The intentional trembling extends to the left arm also, during excitement or other emotion.

The patient has never had a venereal disease. He has never been addicted to the use of alcoholic beverages or tobacco in any form. He has always been well; has always had much to

do in his profession, and has worried and fretted much about his affairs. He has always eaten heartily of all kinds of food. He has not taken physical exercise as a recreation.

For a month he has noticed shortness of breath after exercise, and an unusual throbbing of the heart after exercise, after a hearty meal and when excited. The strength has been noticeably less, and recently the ankles have been swollen in the evening. The tremulousness of the hands has become worse. Vision is less acute. The mind becomes easily tired. He dreads the presence of strangers, and fears to go into court with his cases. He has headache, with a sense of pressure about the head and the nucha.

Examination.—Height, six feet two inches; weight 250 pounds; face pale and eyes puffy; tongue large, pale and covered with a white fur. Muscles flabby; upper extremities tremulous, and this was increased by the excitement attendant upon the examination. Abdomen large, prominent and flaccid. Liver area apparently normal; spleen not palpable. Lungs normal, with a few moist râles over posterior dependent portions. Heart area difficult to ascertain because of overlying lung. Apex beat not palpable. Heart sounds pure but weak. No endocardial murmur. Heart action irregular; intermittent pulse, 96 per minute. No accentuation of second sound over pulmonary or aortic valves. Radial pulse, soft, moderate in size, compressible and intermittent. Moderate edema of both legs. A single specimen of urine showed, sp. gr. 1025, acid reaction, brownish color, small amount of albumin, no sugar, no bile. A few hyaline and granular casts were found in the deposit of the centrifuge.

He was kept quiet at his home upon a simple diet excluding meats. A more extended examination revealed diminution of the urine of twenty-four hours, with a relatively low specific gravity; lessened total solids, and one-half the normal urea. Albumin was constantly present with granular and hyaline casts. The heart presented the physical findings enumerated. The sphygmograph gave a poor and unsatisfactory tracing, because of the difficulty of applying the instrument to a wrist which was in a constant intentional tremor, and also because the heavy muscles and tendons covered the radial artery so fully that the pressure necessary to secure a result gave a tracing of no value. *Streyninae sulphas*, infusion *digitalis* and hydrogogue cathartics were used from the beginning. At first there was apparent improvement. The incompetent heart beat more regularly and forcibly, and the symptoms referable to a weak heart disappeared or became better. The urine increased in amount, but the total solids and the urea remained deficient, the specific gravity low, and the albumin and casts were always present. He resumed his work in spite of protests to the contrary during January. From the beginning of the return to work he gradually relapsed into the condition which he first presented. During February, March and April he became gradually worse, and by the beginning of May he was practically water-logged. There was general anasarca, orthopnea, cyanosis, cough, a weak wavering pulse, feeble heart action without perceptible murmurs, accentuation of the aortic second sound, diminished bulk of urine, containing much albumin and many hyaline granular and epithelial casts, with less than one-half the normal amount of urea. There was sleeplessness but no headache, no nausea

and no disturbance of vision, with normal fundus. The general appearance was that of a chronic Bright's disease, with the pallor, puffy face and heavy expression so characteristic of the disease. On April 20 he complained of pain in the left side of the neck, and within twenty-four hours the left jugular vein, extending from the angle of the jaw to the clavicle, was felt as a cord-like body, which was tender to the touch. This was diagnosed a thrombus, and the diagnosis was verified by an extension of the thrombus into the left axillary and brachial veins. This complication was attended with much edema of the left upper extremity, which continued for about two weeks. Absorption of the thrombus seemed to occur and the circulation was fully restored within a month. During the time enumerated the patient was kept quiet in bed as much of the time as he would submit to. The diet was exclusively vegetable, with some milk. The medication consisted of strychnine sulph. gr. 1/30, every four to six hours. Digitalis in infusion or tincture, off and on, Basham's mixture of iron in 3ss. every six hours, and hydrogogue cathartics, elaterin,—gr. 1/20 to gr. 1/10, every six hours, or the salines in doses sufficient to produce free, watery stools several times each day.

From the time of the absorption of the thrombus of the left external jugular, axillary and brachial veins the patient commenced to improve, and by June 15 he was entirely free from dropsy, the heart stronger, beat almost regularly, and the patient felt able to go about. The urine still contained albumin and many hyaline and granular casts, and a deficient amount of total solids and urea.

He was placed upon a diet for nephritis, excluding dark meats, and the iron and strychnia were continued. He spent the summer at the sea-shore. Upon his return home in September, 1895, his weight was 220 pounds; his color was good, and he felt perfectly well. An examination showed a steady heart action, with a good strong and soft pulse of 84 per minute. The heart presented no abnormal signs. The urine of twenty-four hours was as follows: quantity 56 ozs., sp. gr. 1022; reaction, acid; color, amber; urea 2 per cent. or 537 grains in twenty-four hours. No bile, no sugar, no albumin and no casts.

He was cautioned not to eat much meat, and to not fatigue himself by work.

He returned to his professional work, which was very exacting. He walked, for recreation and exercise, five or more miles per day. During 1896 he remained well. I saw him several times and examined the urine every month. Unusual professional care worried him much during the winter of 1896-7. In March, 1897, he again complained of the dyspnea of exertion, and the heart was not quite regular. There was a trace of albumin, but no casts in the urine at this time. Rest, with strychnia, gave him relief. He was out of Chicago for a vacation during July and August. Sept. 24, 1898, he again complained of dyspnea upon exertion and of palpitation of the heart. Weariness after mental or physical exertion and the old symptom of fear of people returned.

Examination showed some edema of feet and legs, a weak, irregular heart, and for the first time a systolic murmur at the mitral area, not transmitted, with accentuation of both the aortic and pulmonary second sounds. The urine contained a trace of albumin and a few hyaline casts, and a normal percentage of urea.

He was again placed at rest and submitted to the bed with better grace than during the preceding attack. In spite of physical and mental rest, heart tonics, free stools daily and a simple diet he became gradually worse. On December 25 he was suddenly seized with aphasia and slight loss of power in the right leg and arm. Within two hours he could talk incoherently but never regained the power of free expression by speech or writing.

The dropsy gradually increased and the heart weakness more pronounced. The heart murmur remained constant, and there was evidence of dilation of both ventricles of the heart. The urine was, as a rule, scant, from 20 to 40 ounces per twenty-four hours, with lessened solids including urea, but not much albumin and but few casts. In this attack the symptoms pointed chiefly to the heart as the chief offending organ. At no time in this attack did the urine present evidence of more than chronic venous congestion of the kidneys. He died suddenly on March 14, 1898.

The clinical course, the physical signs and urinary findings in this case in the first attack pointed more to nephritis as the primary disease. The thrombosis of the left jugular and other veins, the absence of retinal changes, the primary edema of the left, the absence of the nervous phenomena of uremia, and finally the apparent recovery and status of good health for about eighteen months negatived nephritis. On the other hand, the last named phenomena, the relapse of the disease, the physical findings of the heart and the condition of the urine in the last attack pointed to an intrinsic disease of the heart, as a cause of the insufficiency of that organ.

The difficulty of the recognition of the primary cause of the incompetent heart is the intimate relation which exists between the cardio-vascular system and the kidneys. In all inflammatory diseases of the kidney there are cardio-vascular changes, which are most marked in the so-called granular kidney. These fibroid changes of the arteries and hypertrophy of the heart, when most marked are easily recognized by the physical signs and the characteristic urinary findings. In these cases, too, there is not, as a rule, a tendency to that form of heart incompetency which leads to dropsy. The arteries, palpable and invisible, partake of the fibroid change, and cerebral or other hemorrhage is more likely to occur than dropsy. Headaches, nausea, vomiting, cyclical diarrhea, retinal changes, mental excitement or hebetude of mind, coma or epileptoid convulsions are the rule in the later stages of the disease. In chronic tubal nephritis, on the other hand, while cardio-vascular changes are less marked, dropsy may occur with all the phenomena of an incompetent heart. The pallor of the patient, the puffy, waxy face, the retinal changes, the headache, nausea and vomiting, the cyclical diarrhea, the epigastric pain and pressure or sense of weight, the scant urine containing much albumin, with hyaline, granular, epithelial and fatty casts, with microscopic quantities of blood at times; and frequently all the signs of a dilated heart, with endocardial murmurs and a weak, rapid and sometimes intermittent or irregular pulse are not unusual phenomena.

The incompetent heart of an arterio-sclerosis which involves the coronary arteries alone or of the arteries of the heart and kidneys or of the general arterial system, may present phenomena so nearly like the clinical findings of one or both of the inflammatory condition of the kidneys mentioned that the

differentiation becomes difficult. There may be the thickened artery, the sustained full pulse, the hypertrophied or dilated heart, the retinal changes, vomiting, diarrhea, nervous phenomena, headache, albuminous urine with deficient urea, and the presence of casts of all varieties.

An incompetent heart from valvular disease, presenting first of all the physical findings, characteristic murmurs, dyspnea of exertion, cyanosis, dropsy, beginning in the lower extremities, enlarged liver, portal congestion with consequent indigestion, tendency to thrombosis or embolism, a concentrated albuminous and often bloody urine with hyaline and granular casts, is easily recognized when classical, but may present symptoms and clinical findings which make differentiation from primary kidney disease very difficult. In other words, kidney disease with cardio-vascular changes and an intrinsic heart disease with broken compensation and resulting venous congestion of the kidney, often present common symptoms and signs, which may indicate coincident primary involvement, or a primary disease of the one with resulting disease or disturbance of function of the other. Those phenomena common to both I have already enumerated. There are special phenomena, however, sometimes present, which although sometimes common to the two are more often the result of a primary heart or kidney lesion alone, and these signs or conditions are of some aid in differential diagnosis.

If the urine, even though scant, shows a relatively low specific gravity, with diminished total solids, lessened urea, much albumin and casts of all varieties.

If the arterial fibrosis is marked and the pulse full and sustained, or without arterial thickening if the pulse is sustained.

If the dropsical effusion is poor in albumin.

If the dropsical effusion contain urea in considerable amount.

If there is a tendency to inflammation of serous surfaces, pericarditis and pleuritis especially.

If there is a tendency to persistent morning nausea and vomiting of stringy mucus.

If there is tendency to periodic diarrhea.

If there is much headache, especially severe frontal and occipital pain.

If there is a tendency at one time to unrest and mental excitement or at another to somnolence or to coma.

If cerebral hemorrhage occur.

If the dyspnea of exertion becomes of the Cheyne-Stokes type. If severe epigastric pain occur.

If the eye ground shows the changes common in albuminuria, and if the patient present a pale, waxy puffy face and heavy expression, and a general anemia, the diagnosis is in favor of nephritis.

If there is a history of antecedent disease in which endocarditis may have occurred.

If the heart shows physical signs of valvular disease with characteristic murmurs.

If there is an irregular heart action persistent in character.

If the pulse is weak and not sustained with or without arterial fibrosis.

If the dyspnea of exertion is attended with cyanosis.

If there is a normal amount of red cells and hemoglobin or only a moderate degree of anemia.

If the dropsical effusion begins in the lower extremities, appearing during the day.

If the dropsical effusion is relatively rich in albumin.

If the dropsical effusion contains relatively little or no urea.

If there is a much enlargement of the liver and tenderness of the left lobe.

If the urine is scant, of high specific gravity, with much lateritious deposit, little or no albumin, a high percentage of urea, although the total urea of twenty-four hours is deficient: a few casts only, chiefly hyaline or finely granular.

If there is little or no headache, no eye ground changes, and if venous thrombosis or embolism occur the diagnosis is in favor of intrinsic heart disease.

100 State Street.

DISCUSSION.

Dr. COLE of California—I am much interested in the paper read by Dr. Billings. It is very difficult to decide whether the primary condition is one pertaining to the kidneys or to the heart; this is more especially true in advanced diseases. And I am glad to know that there are others that have this difficulty in making a differential diagnosis.

I am much pleased with the finest points in the differential diagnosis which Dr. Billings has made.

Dr. WEST of Galveston, Texas—It appears to me that this is one of the most interesting and practical subjects. It is a difficult question to determine whether the primary disease is one of the kidneys or of the heart. Diseases of these organs occur so concurrently. One point in the differential diagnosis and which assists in determining which is the primary disease, is the therapeutic test. If renal symptoms due to congestion of the kidney, such as albuminuria and other evidences of disturbed renal circulation appear, the patient should be placed upon proper treatment which tend more especially to remove the results of disturbed cardiac action and disturbances of the circulation; this consists in placing the patient in a horizontal position and giving him heart tonics, such as digitalis, strychnin, etc., and stimulate the emunctories, especially the bowels and skin; under that treatment in many instances the differential diagnosis will clear up. The urine becomes more abundant, there is a lower specific gravity, the casts disappear and the differential diagnosis can be made with perfect ease. In my experience, if these cases are allowed to progress for a long time, it is then impossible to make a differential diagnosis.

Dr. BOND of Indiana—This is an interesting subject. Dr. Billings brought out clearly all the prominent points. In one case the patient had kidney disease and still further arterio-sclerosis. One common factor in both diseases is arterio-sclerosis. I doubt if it is possible to have either disease without arterio-sclerosis: this is a common observation in these cases even before albumin or casts appear in the urine or a heart murmur is observed, showing deficient waste. Some years ago, 100 cases of this kind were observed where there was a deficiency of urea found in cases not suspected of having heart or Bright's disease. I think the first evidence of this disease which is constant is a deficiency in the nitrogenous waste. Instead of twenty-five grams of urea excreted in twenty-four hours, a man was found to be passing ten or fifteen grams; he was afterward found to be passing casts and there were symptoms of arterio-sclerosis: the albumin came on especially after exercise. One year afterward the heart was found to be affected.

Dr. BROWN of Illinois—I think it is very important that we should separate the two great forms of Bright's disease, the interstitial from the chronic. There is no disease in which we so often make mistakes in the early diagnosis as in interstitial

nephritis. For five or ten years there may be no albumin, no dropsy, no casts or anything to account for the polyuria which exists, and it is very difficult to find the cause. The diagnosis is made, not upon the symptoms directed to the kidneys themselves, but upon the symptoms that are referred to other organs than the kidneys—upon the subjective symptoms.

Dr. BRIDGE of California—What Dr. Bond has said is largely true. It is a matter of no great moment in these cases to settle the question whether the lesion is one of the kidneys or of the heart, because sooner or later lesions in both will occur in the same patient. Dr. Billings has set forth, as well as could be set forth, the means of making a differentiation. An important thing brought out in the paper was that there were two kinds of lesions and the fact that they result from similar causes. There is some poison in the blood containing effete matter, which lowers the vitality of the vessels of the kidneys, whereby these various lesions occur. In his case he had afterward a thrombus in the veins due to some injury to the lining of the vein, followed by certain changes in the blood, then atheroma which caused changes in the heart, producing dilatation and finally murmurs. What is this change? What metamorphosis is there in the lining of the vessels of the heart and kidney which make it predisposed to take on these changes?

As to the diagnostic value of casts, I feel sure that if the Doctor should use the centrifuge carefully, he would find casts in everybody's urine. It is no question of the presence of casts, but their number.

Dr. DAVIS of Chicago—The most difficult problem presented to us is to find which is the primary disease, that of the heart or of the kidney; especially is this true when the kidney and heart trouble appear to come on simultaneously. In certain cases the phenomena present enable us to make a diagnosis as to which is the primary lesion. On the other hand, as already has been stated, we find cases in which there are evidences of cirrhosis of the kidney with cardiac lesions, due to atheromatous condition of the vessels generally. Here symptoms come on which are important in that they show us which lesion predominates, whether the renal or the cardiac. These cases require the closest scrutiny and treatment.

Dr. BRIDGE—There were two points brought out in the paper of Dr. Billings, one, heredity, or the family tendency to the disease; second, the occurrence of some persistent disease which could lead to either heart or kidney disease. Frequently Bright's disease is a family disease. Also, the persistence of any disease which could lead to endocardial or myocardial disease would lead to heart disease as against Bright's disease.

The point raised in regard to the thrombus is a good one. Whether it occurs in the blood vessel of the body or the brain it indicates a tendency to heart disease. The non-existence of hypertrophy and valvular lesions in any case would point away from the heart and toward the kidney. In Dr. Billings' case might it not have been that the earlier disease was a diffuse nephritis in a patient with a weak heart which manifested symptoms of this weak heart? Afterwards the patient regained health, and then suffered from cardiac disease which ended his life. I believe that cases of chronic diffuse nephritis recover under appropriate treatment and the evidences of kidney lesion, previously present, will entirely disappear. Perhaps it may recur again or produce changes which will produce manifestations later on in the life of the individual.

I am glad that I have heard the paper; the differentiation between lesions of the heart and the kidney is of considerable importance as bearing on both prognosis and on treatment.

Dr. WEST of Galveston, Texas—I wish to speak of another class of cases of interstitial nephritis in which there is a low specific gravity, with an entire absence of renal symptoms or disturbances of circulation. There are no symptoms at all except a slight albuminuria. By the careful use of the centri-

fuge no casts are found. I examined a man for life insurance, in whom there were no symptoms pointing to kidney disease; there was an albuminuria present. No casts were found after careful examination in several instances. One might suppose it to be a case of temporary albuminuria. I could not possibly recommend the man in spite of the fact that he gave no symptoms at all.

Dr. BABCOCK of Illinois—I should like to emphasize a single point in the differentiation between primary cardiac and primary renal cases; it relates to pulse tension. In these cases of primary renal disease there is an increase in the blood pressure which will have existed for a greater or less length of time, and if the pulse be carefully studied both by the sphygmograph and by careful auscultation of the aortic second sound much valuable information will be derived. In the case reported it was distinctly said that the primary examination of the heart showed an accentuation of the aortic and pulmonic second sounds. It seems to me that that statement was important. At the postmortem it was shown that the heart had been diseased for a long time, although the patient suffered from renal changes, as has been stated; perhaps there was a chronic diffuse nephritis which was recovered from; still the heart was the organ primarily at fault.

I have under observation a man aged 65 years who has an enlarged heart, who has renal changes, whose urine shows evidences of chronic interstitial nephritis. The arteries are also sclerosed. It has been a difficult matter for me to determine which organ was the one demanding treatment. The accentuation of the aortic second sound, the pulse tension and the fact that the heart endures exercise, also that the amount of urine responds pretty well, *i. e.*, the amount of the urine increases but the solids of the urine do not, these findings make me sure that in this man's case the heart is not the organ primarily affected. The heart is secondarily enlarged in response to the abnormal pulse tension which has existed for years. The treatment in such cases, to be successful, must be directed to the general condition largely, although if the heart is disproportionately weak, then this organ demands close attention and the greatest care.

Dr. ANDERS of Philadelphia—The subject of Dr. Billings' interesting paper is a large one and I simply would like to refer to one or two aspects of the same. The differential diagnosis, as drawn by the author of the paper, readily permits a differentiation of chronic parenchymatous nephritis and organic disease of the heart. Closely with the relationship between the heart and kidney disease stands another condition, namely, arterio-sclerosis. I should like to emphasize the fact that in cases of so-called interstitial nephritis in which lesions of the heart are associated they are from one common cause. One primary fundamental cause is general arterio-sclerosis. Now, the troubles with the kidneys are secondary to the arterio-sclerosis; the same is true of the cardiac condition. In either case compensation ruptures and the left ventricle begins to weaken. In the case reported by Dr. Billings this occurred; the left ventricle was already weakened and so the phenomena reported appeared secondarily. This exists in cases in which primary condition of arterio-sclerosis is followed by rupture of compensation. Few are seen for the first time until after compensation has ruptured; here the presence of organic murmurs can be differentiated from murmurs due to primary valvular disease.

Dr. BILLINGS—I chose this subject because it was very interesting to me, partly because of the difficulty in the diagnosis of these cases, as already has been stated in the paper. It is quite important that a differentiation should be made. A man with an incompetent heart due to intrinsic heart disease, in some cases with a water-logged condition, may be given a hope of prolongation of life. In kidney disease do not forget that when the disease of the kidney pro-

gresses to such a stage that the heart becomes incompetent and the cardio-vascular changes are sufficient to produce this water-logged condition, the patient can not long exist. It is true that therapeutic tests may be of value, but the therapeutic test is like the dead-house test. A man with kidney disease with changes in the heart and blood vessels, who is in a water-logged condition, does not have perfectly normal urine, as can be proven. If a nephritis occurs and continues long enough to have cardiac changes, incompetent heart, bronchitis, general anasarca, etc., he may have hemorrhages in the brain and elsewhere. There has been a condition mentioned in which arterio sclerosis, hypertrophy of the heart and sclerosis of the blood vessels, and other evidences of Bright's disease occurred and yet no Bright's disease. I have tried to write my findings of the case, and also stated in my conclusions that in kidney disease the arterial sclerosis was marked and the pulse full and sustained. I am gratified that the paper has received the amount of discussion it has.

DIABETIC GANGRENE.

Presented to the Section on the Practice of Medicine at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY N. S. DAVIS, JR., A.M., M.D.

PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE, NORTHWESTERN UNIVERSITY MEDICAL SCHOOL, ETC.

The following cases of gangrene associated with diabetes which have been observed by me during the last few years, inspired me to look through the rather meager literature of the subject with care.

J. G., 62 years old, was a ruddy and hearty Englishman, who was habitually careless and negligent of himself and his health. In July, 1892, I found that he was a diabetic. As he promptly improved, gaining in strength and flesh, he did not persevere with the prescribed treatment. He was not seen a second time until September. The last joint of the middle finger of his left hand was then purplish red, swollen and painful. The skin on the ball of the finger was hard, slightly wrinkled and almost black. Pain was constant but not intense. The rest of the finger looked normal except at the first joint a red line of demarcation was discernable. This finger had not been scratched or injured. The gangrene was evidently spontaneous. His urine contained 1.3 per cent of sugar and had a sp. gr. of 1.032. A week later he voided 2 quarts of urine, a quart less than before. It contained only a trace of sugar. Sensibility was entirely wanting in the last phalanx of the affected finger except at the sharply defined line of demarcation. The last phalanx was blue-black and perfectly mummified. Pain gradually disappeared. By the 24th of September the quantity of urine voided was normal, having a specific gravity of 1.028 and containing no sugar. Sugar did not reappear until the end of October, when it occurred in 1.3 per cent. The urine had a specific gravity of 1.031. For several days prior to this examination he used farinaceous food freely. When he again adhered to a moderately rigid diabetic diet, sugar disappeared from his urine. The last phalanx gradually underwent spontaneous amputation and separated completely from the healthy tissue the first of November. The stump healed nicely. I saw him occasionally during the next three months. He gained in flesh, strength and vigor. There was no return of glycosuria, although in January he suffered from a mild eczema of prepuce and crotum. This man had tortuous temporal arteries and nodulation of the left radial. A sphygmographic tracing showed below round-topped waves produced by atheromatous arteries. When his finger was first found to be gangrenous amputation was advised, but he refused to submit to it, and when he learned later that spontaneous amputation might take place, was still more unwilling to have the knife used.

B. J. B., 62 years old, a lawyer of prominence in one of the smaller cities of Michigan, consulted me in November, 1894. He first learned that he had glycosuria in 1892, when he was examined for life insurance. He was a large eater, moderate drinker, and eminently sedentary in habits. Ten years before he weighed 200 pounds; when he was first seen by me he weighed 177. For two years he had not varied more than two or three pounds from this weight. He felt in good health, except that for some months there had been an ulcer on a callous

spot on the ball of his right great toe. An offensive slough of small dimensions had separated from it. When I saw it healing had begun. There was a shallow ulcer in the center of a yellowish callous. Almost no pus came from it. It caused no pain and was only tender when the raw flesh was touched. The toe appeared healthy. A sample of his urine had a specific gravity of 1.040 and contained 2.5 per cent. of sugar. His arteries were hard but not nodulated. His heart was not hypertrophic.

I did not see this patient again until September, 1895. The ulcer under his toe never healed entirely. Several times it seemed almost well but became worse again. Alongside of the callus on which the ulcer was located was a superficial blister filled with bloody serum. He had recently had a similar blister on the sole of the foot. Both had come without recognizable cause. His urine contained a trifle less sugar. His general health was good; he weighed 180 pounds.

The next visit I received from him was in June, 1896. The ulcer remained unhealed. It was sometimes scabbed over and at others was covered by a small amount of pus. Its diameter varied from one-third to one-half of an inch. A sample of his urine contained 3 per cent. of sugar. In October of the same year, this patient was seen again. He thought his toe was well until about the first of September, when he was much worried by business cares and lost flesh, the ulcer opened again, and in a symmetrical place upon the left big toe a large blister formed. When the latter was opened and the dead overlying skin removed, a considerable excavation with raised edges and suppurating surface was disclosed. I did not see him again for a year, until last October. Both ulcers were about the same. The whole of the left big toe was purplish and slightly swollen. It was moderately tender and painful. In other ways he felt well. A sample of his urine had a specific gravity of 1.033 and contained 2 per cent. of sugar.

This patient was seen by me at such long intervals that he can not be said to have had systematic treatment. Moreover, he was not abstemious as regards food, drink or tobacco. He kept the affected toes as clean as possible, and applied successively a great variety of antiseptic salves and powders. He had persistent glycosuria, but of very moderate grade of severity. He rarely made more urine than was normal, and the diabetic state caused no appreciable loss of flesh or ability for mental work. This case is interesting because of the character and chronicity of the ulcers, and finally, because of the symmetrical distribution of the ulcers upon both feet. When last seen by me, I feared the whole of the left great toe was about to become gangrenous.

Katherine E., 58 years old, born in Ireland, was first seen by me in July, 1895. For five months her right foot pained her. I found the toes and, to a less extent, the distal third of her foot reddened and painful. The pain ceased almost completely whenever she remained on the bed or lounge. There had been slight suppuration about one toe nail, and a superficial ulcer on one toe joint. Both these lesions had disappeared before I examined her foot. She had lost flesh during several months. She had never been stout, but was decidedly thin when she came to me. Her appetite was poor. She experienced no thirst. Her bowels were constipated. As far as she had observed her urine was normal. A week later the foot was less swollen and painful, but the toe next to the little one was numb, purplish red and looked as if about to become gangrenous. A sample of her urine had a specific gravity of 1.028, and contained 1.5 per cent. of sugar. Before the end of August the last two phalanges of this toe were mummified. A line of demarcation developed at the second joint. On the toe next to the big one a moist slough formed over a space a quarter of an inch in diameter. She was making from three to four pints of urine daily. The glycosuria rapidly diminished and by the first of September ceased. Her foot remained about the same, causing varying degrees of pain. Slowly the mummified toe separated from the healthy tissue. The middle of December it was attached only by a few shreds of tissue, which separated with a little traction. The ulcer on the other toe was slowly improving. The stump of the amputated toe soon healed perfectly. A trace of sugar was discoverable in her urine at this time. In January the ulcer on the second toe grew worse, although there was no glycosuria. By the first of February it had opened into the joint. Toward the end of the month I picked from the opening a small piece of dead bone. After this the wound slowly healed. In March, the following month, a gangrenous slough formed on the ball of the great toe of the same foot. The whole foot from the instep to the toes was a dull purplish red. The toes were slightly swollen. The capillary circulation was extremely slow in the skin of the foot. Pain was not constant or considerable. Her urine contained a trace of sugar. During the summer she was comfortable, able to work and rarely troubled with pain in her

foot. In October her left foot (not the one first affected) became painful. The second toe was purplish red. From one edge of the nail it bled slightly. A red streak stretched up to the instep from the base of this toe. Her urine contained about 1 per cent. of sugar. The foot became diffusely red and more painful, the second toe lost sensibility, one edge sloughed away, the remainder slowly mummified. A month later this toe began to separate from the sound flesh and the one next to it also became gangrenous and dried up. The foot improved and was only occasionally painful. She kept her leg in a horizontal position almost continuously. Two months later both toes came away, having undergone spontaneous amputation, one at the first joint the other at the second. This woman also refused amputation by the knife.

In this case the disappearance of sugar from the urine, while the mummified toes were separating from the healthy tissue and its reappearance just before and when gangrene began afresh, was noticeable. The superficial arteries of this patient were tortuous and hard, but not noticeably atheromatous. Nor were there changes in the heart which would suggest the possibility of extensive atheroma. Undoubtedly, however, atheroma existed in all three of these cases and was the prime cause of gangrene.

The first and third cases typify well the milder forms of spontaneous gangrene in diabetics. The successive invasion of different toes in the last case is noteworthy. The diminution and even disappearance of glycosuria in both cases, while mummification existed and spontaneous amputation of the phalanges was progressing, is interesting. A similar marked diminution or disappearance of glycosuria I have observed in several cases when tubercular disease of the lungs was active. Both cases were upon diabetic treatment, which consisted mainly in a regulation of diet, the use of arsenical preparations and at times opiates.

The second case at first was one of *mal perforant*, which is an occasional complication of diabetes. Kirmisson (*Arch. gén. de Méd.*, 1885) has reported seven cases of it associated with diabetes; Duvernoy (*Arch. gén. de Méd.*, Paris, 1891, 603), four; Gascuel (Thesis, Paris, 1886), fourteen; and Williamson, four ("Diabetes Mellitus," R. T. Williamson, published by Y. J. Pentland, London, 1898). Gascuel found in ninety-one cases of *mal perforant* that it was associated fourteen times with diabetes. The association is evidently no more an accidental one than the association of diabetes and gangrene proper. That there is a more frequent association of gangrene and diabetes than chance would cause, was first pointed out by Marchel in 1852. Diabetic gangrene occurs much oftener in the legs and feet than elsewhere. Marchel makes note of thirty-five cases with the lesion below the knees, seven in the lungs and three in the hands, out of a total of 133. In the remaining cases the lesions were very widely scattered. Hunt records three out of five cases of gangrene of the feet. In the cases which I find reported still more recently there is about the same proportional distribution of the lesion.

Sturgis (*Bos. Med. and Surg. Jour.*, 1891, 261, cxxiv) has described an interesting case of gangrene of the lip in a diabetic of 64. Sloughing occurred, but the wound finally healed. For three years the secretion of saliva had almost ceased in this patient's mouth, a condition which caused him great distress. During the period of inflammatory reaction after gangrene had occurred on his lip, saliva formed once more in his mouth. In this case Sturgis calls attention to the great diminution of sugar in the urine after sloughing had occurred. Those cases of gangrene occurring in the course of diabetes which are associated with or superimposed upon inflammation,

are undoubtedly chiefly due to the low vitality of tissues in diabetics, and the consequent ease with which putrefaction takes place in them. The frequency of gangrene of the lungs in diabetics, who also have tubercular or other disease of the lungs, can be accounted for in this way. The cause of spontaneous gangrene, which is not preceded by visible wounds or infection, is of more interest. Neuritis and atheroma have both been assigned as causes of the spontaneous gangrene of diabetes. Both lesions frequently accompany diabetes. Godlee (*Med. Chi. and Trans.*, lxxvi, 37) admits two varieties of spontaneous diabetic gangrene, the one due to neuritis, the other to atheroma. He recommends amputation at the knee, or above, in all of the latter variety, and operation close to the point of necrosis in the former. Davies Pryce (*Brain*, 1893, 63) points to the almost constant coincidence of neuritis and atheroma in diabetes. Heidenhain's review of this subject is the most thorough of any in recent years (*Deut. Med. Woch.*, 1891, xvii. 1097, 1111, 1123, 1144, 1163). He believes that diabetic gangrene is in most, if not in all, cases due to arterio-sclerosis. His statistics are quite convincing. According to him, spontaneous gangrene in diabetics is pathologically identical with senile gangrene. Heidenhain also calls attention to the very frequent occurrence, even in early adult life, of arterio-sclerosis in diabetics. The cases which I have found reported are all in that period of life when this arterial lesion is to be expected. The only cases in earlier years of life are one, a girl of 19, in whom gangrene developed after an operation for cataract, and one of gangrene of the lungs in a child 8 months old (E. Wegli, *Arch. für Kinderheilkunde*, B. xix). In many of the cases of diabetic gangrene on record no mention is made of the condition of the arteries. In all in which mention is made of the state of the arteries, arterio-sclerosis existed, with one exception, which was a case described by Rosenblath (*Arch. für Path. Anat.*, Berlin, 1888, cxiv, 202-210). Very numerous areas of circumscribed necrosis occurred upon the skin and mucous membranes of this patient. No vascular lesions were discernible at autopsy. Hebb (*Westminster Hosp. Rep.*, lx, 1895, 113) describes another noteworthy case, which shows that every time gangrene occurs in diabetics, it is not due to either neuritis or arterio-sclerosis in the affected limb. Gangrene of the right arm developed with the symptoms usually caused by embolism. At the autopsy it was found to be due to an embolus consisting of a vegetation which had broken from an atheromatous ulcer in the arch of the aorta. Arteritis was general, but beginning, not advanced.

Williamson thinks that perforating ulcer of the foot in diabetes is due to neuritis. He bases his belief on clinical, not postmortem evidences. Mild neuritis is extremely common in diabetes and occasionally a severe form of lesion is demonstrable. In case two, just described above, frequently indistinguishable, uneasy and uncomfortable, but not painful sensations are felt in the legs. He had no knee jerk. There may be evidences of mild neuritis. Most frequently neuritis and arterio-sclerosis occur together.

Hunt says that areas of gangrene in diabetics are mapped out by a less defined line of demarkation than in cases of senile gangrene. The literature of the subject does not corroborate this statement, nor do my own observations.

Surgeons have been disinclined to operate upon

diabetics because of their susceptibility to infection. Recent experience has shown, however, that amputations can be performed upon them with good success, provided only sufficient care is taken to prevent infection. Heidenhain (*Deut. Med. Wochen.*, 1891, xvii) recommends that if gangrene is confined to the toes the physician wait until a line of demarkation develops, and if there is no evidence of general infection, that the dead tissue be allowed to separate spontaneously. If, however, the sole or dorsum of the foot is involved, the leg should be amputated at the knee or above it. This is a rule which my reading convinces me is correct. I, however, think that amputation of the toe, after a line of demarkation has become well established, is preferable to the tedium and pain of spontaneous amputation. The greatest pains should be taken to gently remove the sloughing tissues, and by the free use of antiseptics to limit putrefaction.

It goes without saying that the diabetes should receive as much attention as the gangrene. Treatment appropriate to it should be carefully carried out.

THE DIFFERENTIAL DIAGNOSIS BETWEEN DENGUE AND YELLOW FEVER. WITH SOME ACCOUNT OF THE EPI- DEMIC OF 1897 IN TEXAS.

Presented to the Section on Practice of Medicine at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY H. A. WEST, M.D.

GALVESTON, TEXAS.

The diagnosis of disease is universally and justly regarded as the foundation stone upon which rests the entire superstructure of practical medicine. The question concerns the health, life or death of the individual affected, his family and friends, the public in so far as he may be a useful and influential member of society, and the physician as affording a basis for his prognosis and treatment. But there are occasions when far more momentous interests are involved in the correct diagnosis of prevailing diseases: a complete paralysis of commerce, the wheels of industry arrested, enforced idleness with consequent poverty and suffering of thousands, enormous depreciation in property values of every kind, universal fear and panic, and the possibility of wide-spread death and desolation. To the physician himself an error in diagnosis ordinarily involves results which are comparatively inconsequential; on the other hand, there are times when such an error means public denunciation and disapprobation. A correct diagnosis, even

when opposed to commercial interests, may involve him in losses of reputation and business which may last for a lifetime.

This was the state of affairs in Texas during the summer and autumn of 1897. So long as yellow fever was supposed to prevail east of the Mississippi only, and that dengue was the epidemic disease in Texas, peace reigned; but when the trouble came to our own doors by the announcement of yellow fever in Galveston and Houston, there came the contest over the question of diagnosis, with visits of local experts from city to city, the gradual passing of the epidemic with no record of deaths from yellow fever, and the popular conviction of a stupendous error committed by those who believed in the presence of that disease. The majority, both of physicians and laymen in the State are firm in the conviction that dengue was the disease which was prevalent in Texas during the past summer; a minority believe that yellow fever also prevailed, but that owing to its mild form, indisposition to spread, exceptionally small mortality and resemblance to dengue was usually unrecognized. Confusion has arisen in the minds of many. They ask themselves, "Are the land-marks all swept away? Have the authorities led us astray? Has a new disease, *anomalous dengue*, made its appearance? Is there no such thing as dengue? Is the so called dengue a mild form of yellow fever? Does the latter arise de novo?"

The important issues dependent upon a knowledge and recognition of the truth upon these points render it not only pertinent but imperative upon the part of those who are familiar with the facts to study them in concert. Now that the obscuring mists due to commercialism, prejudice and passion, have for the most part passed away, we approach the subject from a scientific standpoint. It is with this end in view and in no spirit of dogmatism or self-assertion that I introduce the subject for consideration.

The following hypotheses have been assumed in relation to the recent epidemic:

1. The disease was dengue only. There was no yellow fever in Galveston, Houston, or the State of Texas in 1897.

2. There were anomalous cases of dengue, presenting all the symptoms of yellow fever, but proven not to be that disease, by the indisposition to spread from numerous foci and the low mortality rate.

3. During the progress of an intense epidemic of dengue throughout the State, in Galveston, Houston, and possibly other places, yellow fever made its appearance, and in consequence of its mild form and resemblance to the prevalent disease was generally unrecognized.

4. An imputed hypothesis that the epidemic of 1897 in Texas was yellow fever only.

5. A few cases terminating fatally, and others attended by marked jaundice and albuminuria were denominated acute infectious jaundice (Weil's disease).

In order to obtain definite information upon the subject, the following circular of inquiry was distributed to a limited extent. I regret very much that replies could not have been obtained from every infected place in the State, so as to have made the report an exhaustive one. The subjoined tabular statement, will, I trust, afford sufficient data upon which to base some definite conclusions. Following is the circular of inquiry:

"It is my intention to prepare a paper upon the 'Differential Diagnosis between Dengue and Yellow Fever, with some Account of the Epidemic in Texas in 1897,' to be read at the forthcoming meeting of the State Medical Association at Houston, and at the Denver meeting of the AMERICAN MEDICAL ASSOCIATION. If dengue prevailed in your community during the last season you would oblige me very much by furnishing me with information upon the following points:

"1. Date of outbreak; rapidity of spread; probable proportion of population affected; duration of epidemic; any evidence as to its origin.

"2. Any unusual meteorologic influences, as excessive heat or precipitation; local hygienic conditions.

"3. Symptomatology: *a.* The eruption: The character of, and present in what proportion of cases. *b.* Glandular enlargements: What glands usually involved, and in what proportion of cases. *c.* Hemorrhages: In what proportion of cases and from what sources. *d.* Nausea and vomiting: Severity and comparative frequency of; dysenteric symptoms noted. *e.* Albuminuria: In how many instances examined for, proportion of cases found, large or small amount; any other characteristics of urine noted, daily quantity, color, casts, blood, epithelial cells; any uræmic symptoms or other evidence of acute nephritis.

"4. Ratio of pulse to temperature.

"5. Jaundice, if noted, character of, and occurring in how many cases.

"6. Mortality, postmortem findings, if any.

"7. Did you have any reason to suspect the presence of yellow fever? If so, upon what evidence?

"8. Any difference in the severity as the epidemic progressed?

"As I am sending out but a limited number of these circulars, and the subject is of extreme interest and importance, a prompt and complete reply is requested."

Subjoined is a tabular statement of replies:

Data obtained from other localities are as follows: Gainesville, Cook County, on the extreme north central border, reporter Dr. J. E. Gilcreest, no epidemic, only a few sporadic cases of mild type, symptoms not noted. Terrell, Kaufman County, near N. E. border; Dr. W. H. Monday reports no cases. Dr. J. T. Wilson, Sherman, Grayson County, north central border, no dengue. Dr. J. M. Neil, Bonham, Fannin County, in same district as above, no epidemic; saw but one case, which was contracted at Paris. Dr. T. J. Bell reports from Tyler, Smith County, East Central Texas, very mild epidemic, commencing 15th of October, spreading slowly and affecting a small number, no evidence as to origin, no rash in most cases; no hemorrhages, glandular involvement, dysenteric symptoms or jaundice noted; no deaths.

Dr. J. H. Barham, Nacogdoches, east central; no epidemic, saw three cases only; one contracted dengue in Houston, two here, all in different families, no spread, eruptions in two, absent in one, nausea and vomiting in all; no tests for albumin; jaundice in all, well marked in one, moderate in one, slight in the other; suspected yellow fever in case from Houston; all recovered.

Summarizing results obtained from the foregoing twenty observers in eighteen places, we find as follows:

The epidemic of dengue of 1897 prevailed chiefly in southern central Texas within a radius of 200 miles from Houston, but extending and prevalent to a limited

extent 300 miles to the extreme northern border. San Antonio, Houston and Galveston, followed by Schulenberg and Navasota, appear to have been most intensely infected, the proportion of population in these places affected varying from 75 to 90 per cent. Belton, Palestine and Huntsville followed closely with a percentage of 60-65. In the extreme northern and eastern portions of the State, as in Gainesville, Sherman, Bonham, Terrell and Tyler, there were but a few sporadic cases. At Dallas and Paris a very mild epidemic, affecting not more than 6 per cent. of the population. San Antonio, Galveston and Houston seem to have been the centers of infection, as appears from the following statement. Palestine, a railroad center about 150 miles north of Houston and 200 miles northeast of San Antonio, with double daily train service. Dr. Link states the probable origin was from these two cities.

Dr. Tabor reports from Bryan, which is about 100 miles from Houston with direct rail connection, that both the first and second cases were persons who had been exposed in Houston.

Dr. Thomason reports from Huntsville, about seventy miles north of Houston, with direct train service with the latter place and Galveston, that the first case was a young lady from Galveston, and that other foci of infection were soon developed by parties from Houston and Galveston. Austin's first case was a hotel clerk recently returned from San Antonio.

Dr. Lee reports from Galveston that his first case, seen July 29, was from San Antonio.

The first two cases seen by the writer, August 11, were in the persons of young men who had returned to Galveston from the Interstate Drill at San Antonio. Schulenberg is about equidistant from Houston and San Antonio, and may have been infected from either. Navasota is only about seventy miles from Houston. The intensity of the disease at San Antonio, the presence there of militia companies, not only from numerous points in the State, but of States east of the Mississippi, the coincidence in time (latter part of July) of the return of the militia to their homes with the outbreak of the disease, and the positive identification of the first cases in several places in persons who had returned from the encampment, is evidence going to prove that San Antonio was the initial point of infection in the State. As to the origin of the disease in the latter city I have no means of tracing it, but can only say that ample opportunity for conveyance of dengue was afforded by the collection there from July 19 to 26 of troops and visitors from points east of the Mississippi where the disease had made its appearance.

Further confirmation is also afforded by the facts above cited that dengue is an infectious, a portable and contagious disease, *i. e.*, the specific micro-organism which produces it may escape from the body of an infected individual and be transmitted by persons and things to other persons, thus speedily multiplying foci of infection and accounting for the rapidity of its dissemination. The fact previously observed that the progress of the disease is arrested by the advent of cold weather or frost, has also been confirmed by the consensus of statements herein presented. As to the effects of meteorologic and hygienic conditions, the majority of observers describe the weather as excessively hot and dry. The mean daily temperature in Galveston was nearly 8 degrees hotter during the month of October, 1897, than in the pre-

vious three years, and the continuance of unusual hot weather in November and December was the subject of general comment. Local sanitary conditions do not appear to have played any important part in the propagation of the disease. Dr. Paschal, however, calls attention to the excessively insanitary condition of San Antonio at the time of the outbreak, and Dr. Tabor ascribes the comparative immunity in Bryan (only 100 cases out of a population of 4000) to the extraordinary precaution to better the sanitary condition of the town. In regard to the symptomatology, I have not attempted to obtain information as to the complete clinical history of the cases under consideration, but rather to determine the distinctive value of those symptoms which have heretofore been regarded as of great importance in the differentiation between dengue and yellow fever, viz., the presence of an eruption, hemorrhages, nausea and vomiting, evidence of an acute nephritis, as albuminuria, scantiness, presence of casts, uremia, divergent pulse and temperature, jaundice and mortality.

There is almost perfect unanimity upon the part of observers as to the presence of an eruption, the proportion with this symptom varying from 25 to 90 per cent.; 75 per cent. would be a fair average. It is variously described as miliary, scarlatiniform, rubeoloid, erythematous, reddish papules, macular dermatitis, urticarial, desquamative, as localized upon the face and neck, upon the face and upper part of the body, with profuse perspiration, irregular as to time of appearance, coming on the second or fourth day, or end of the fever, hyperemia appearing on the first day. Dr. Peeples notes the fact that, while frequently absent in adults, an eruption was almost invariably present in children.

The consensus of opinion is that glandular involvement occurred to a very limited extent in this epidemic; the majority of observers not noting this symptom at all, but one observer mentioning enlargement of the cervical glands and tonsils in 25 per cent. of the cases; another the connection between enlargement of these glands and the rash; another observed swelling of parotids, sublingual, inguinal and suboccipital, especially in children; one observer noted enlargement of the submaxillary glands in 20 per cent. of his cases.

Hemorrhages.—With but three exceptions every observer noted the occurrence of hemorrhages. The nose, throat, gums, stomach, intestines, uterus and kidneys were the chief sources mentioned. The percentage in which this symptom was present varied from 1 to 10 per cent. Three or four observed black vomit.

Nausea and vomiting were notable symptoms and occurred in a large proportion of cases, varying from 80 to 90 per cent.; with but few exceptions it was described as severe, excessive, incessant, almost universal, etc.

Condition of the urine.—Unfortunately, observations pertaining to the urine were made so infrequently and imperfectly as to render them of but little value. Most of the observers made no examination at all, a few examined for albumin only in the worst cases. Dr. Wilkinson of Galveston, out of 500 cases, says he tested for albumin in many and found it absent; sp. grav. was generally high. Dr. Lee, Galveston, states he examined for albumin in 50 cases out of 490. Eight of these had previous kidney trouble; of the remaining 42, 20 showed slight

albuminuria on the third and fourth days; and in 6 albumin was present in large amounts. Dr. J. M. Coble, Dallas, examined the urine in 25 per cent. of his cases and found slight albuminuria in 10 per cent. of them.

Drs. Wilson and Harris of Navasota only made urinary examinations toward end of the epidemic, in about fifty cases; in forty of these albumin was found in good quantity. The urine was diminished in quality and high colored; casts and blood cells found in three cases and uremic symptoms in four. Dr. Taylor Hudson, Belton, tested the urine only in a few suspicious cases and found albumin in several; the urine was usually dark and diminished; uremic symptoms pronounced in several. Dr. D. L. Peeples, Navasota, found albumin from slight trace to abundance, in some cases with almost total suppression, color varying from a deep straw to color of blood. Dr. R. R. Walker, Paris, found albumin in 25 per cent. of his cases. Dr. W. W. Walker, Schulenberg, only tested for albumin in worst cases; found it in ten, in some in large amounts. The remainder of reporters failed to note condition of the urine.

If, however, dengue was the only disease prevalent, albuminuria is not the rare symptom in that disease as heretofore has been the opinion.

Ratio of pulse to temperature.—Ten out of sixteen observers mention that the pulse was abnormally slow in proportion to the pyrexia; three state the ratio normal and three made no note of the symptom.

Jaundice.—Four reporters mention this symptom as present in about 7 per cent.; one, Dr. Wilkinson, Galveston, mentions jaundice as being of frequent occurrence and of severe grade after October 1. One notes it as generally present of mild grade; another states it was mild in 10 per cent. and severe in 2 to 5 per cent.; one found it more or less present and seven failed to note icterus at all.

Mortality.—There is almost perfect unanimity as to want of mortality in the recent epidemic, the few deaths occurring were usually ascribed to some complication. As regards progressive severity a majority state there was no marked difference; a few assert aggravation in the beginning and in the midst of the epidemic. Dr. Wilkinson notes mildness in August, increased severity in September, progressing to violence in October. Only two or three out of the twenty suspected the presence of yellow fever. As to the early symptoms: The onset was usually sudden, attended by slight rigors or chilly sensations with more or less severe headache and pains in the back, limbs and joints. As regards the paroxysm there is a remarkable discrepancy in the statements of Drs. Lee and Wilkinson, each of whom treated about five hundred cases. Dr. W. (I quote his exact language) states: "The fever in all my observations contained but one single paroxysm; there was no secondary fever from first to last; it departed by lysis, after three or four days duration and never returned, except in cases of relapse several weeks later." Dr. Lee, on the contrary, says: "In a large proportion of the above mentioned cases two paroxysms were noticeable, the first coming on usually without positive chill or chilliness; temperature usually high in the beginning became, after slight remission, high again toward the end of the attack."

It is difficult to reconcile such contradictions. The probabilities are that there is no invariable rule in regard to the paroxysm. In ten cases at the Sealy

hospital, where careful thermometric observations were made, there was one paroxysm only in seven; in one there was an exacerbation in the afternoon of the day following that, when the temperature reached normal; in one the fever was of remittent type, rising at midday for three successive days; in one there was a slight return of fever on the evening of the first day after the temperature reached normal.

Before proceeding to make any deductions from the foregoing, it will be instructive to present a brief review as to the statements of authorities upon the differential diagnosis of the two diseases under consideration. An authority upon this subject I understand to be one who has had the opportunity of studying them at the bedside. I shall not attempt any complete bibliography, but the following I think will show what has been the accepted teaching:

H. D. Schmidt on dengue, *Pepper's System of Med.* Ed. 1885, page 884-885, says the temperature steadily rises in yellow fever, it is remittent in dengue; pulse in yellow fever falls on third day, while the temperature continues to rise, in dengue on the contrary the pulse rises with the temperature. In the condition of the stomach also dengue considerably differs from yellow fever, for while in the latter disease this organ is almost always irritable, and vomiting frequently present, it is but rarely affected in dengue. The urine in yellow fever very frequently contains albumin as soon as the third day, in dengue almost never. Finally the absence of jaundice and the appearance of the eruption on the fourth or fifth day removes all doubt about the nature of the disease.

Sternberg on yellow fever, *American System of Med.*, Vol. 1, page 290: "If a diagnosis has not been made before, the symptoms which characterize the second period of the disease should serve to differentiate it from all forms of malarial fevers. The cool and usually moist skin, the abnormally slow soft pulse, the gastric distress, and pain on pressure in the epigastrium, the yellow tinge of the conjunctiva, and the albuminous urine in a patient whose temperature is normal or subnormal, following a febrile paroxysm as represented in charts, certainly furnish a clinical picture which should be recognized." Speaking of dengue, page 291-92, he says: "It also is characterized by a febrile stage of comparatively short duration, but the characteristic symptoms of yellow fever are absent. Albuminous urine, stage of depression, hemorrhages, etc."

Matas, *Keating's Cyclopedic*, Vol. 1, page 894, quotes Holliday who makes a comparison of the symptoms of the two diseases after a careful analytical study of the opinions of over sixty physicians who had a long experience of both diseases in New Orleans and other parts of Louisiana as follows:

YELLOW FEVER.	DENGUE.
Temperature rising regularly.	Temperature rising irregularly.
Tongue white center, red edges pointed.	Tongue broad white indented edges, rarely red.
Stomach irritable, vomiting frequent.	Vomiting rare.
Conjunctiva congested, jaundice appearing early.	Conjunctiva rarely red, jaundice never observed.
Secretions all suffering, urine scanty, often albuminous, suppression frequent.	Secretions natural, urine usually normal, sometimes exceptionally traces of albumin.
Hemorrhages frequent and alarming, black vomit an urgent symptom.	Hemorrhages slight, black vomit very rare.

In regard to the condition of the urine in dengue,

Matas observes (see foot note, page 889, Keating) "that in tropical pyrexia it is always a matter of great importance, both from the diagnostic and prognostic standpoint." The earliest observers of dengue satisfy themselves with noting simply the color, quantity and reaction, and these are usually most diversely described. Other observers are, however, much more satisfactory. Thus Morgan noticed a specific gravity 1004 to 1040, acid, *non-albuminous*; Chipperfield, acid, sp. grav. av. 1010, *non-albuminous*. Goodeve detected an occasional trace of albumin in four cases in the Indian epidemic of 1853, while Charles and Martialis *never detected* it in the epidemic of 1872. In China at Amoy, Muller and Manson *failed to find albumin*. Albuminuria was detected *only once* in the epidemic of Martinique in 1860, and twice in Cochin China by French observers in 1875 (Mahe). Albuminuria was observed exceptionally by Holliday and his co-laborers (loc. cit.) in Louisiana. Enough has been said to prove that albuminous urine is an exceptional occurrence in dengue, which differentiates it markedly in this respect from yellow fever."

Eugene Foster, *Ref. Handbook Med. Sciences*, Vol. 2, page 397, gives the following summary of the points of similarity and dissimilarity in dengue and yellow fever.

"In time of appearance, and generally in geographical distribution they seem related to one another. Dengue has, however, prevailed in Asia and Egypt, where yellow fever is unknown. Both diseases are arrested by severe frosts. Both dengue and yellow fever are diseases characterized by one febrile paroxysm." In order to show contrast, the symptoms will be arranged in parallel columns:

YELLOW FEVER.	DENGUE.
The fever rises steadily.	The fever rises regularly until the acme is reached, when a short stadium of a few hours occurs, followed by a remission, when a second rise of temperature takes place, but not reaching the former height.
The pulse becomes slower, while the temperature rises.	The pulse increases in frequency with the rise of temperature.
Fever lasts seventy-two hours.	Fever lasts five to eight days.
Vomiting frequent.	Vomiting rare.
Eruption rare.	Eruption common.
Jaundice almost invariably present.	Jaundice extremely rare.
Urine scanty, frequently albuminous and often suppressed.	Urine generally high colored, normal in quantity, free from albumin and never suppressed.
Hemorrhages frequent, alarming and often fatal.	Tendency to hemorrhages from nose, gums, bowels, lungs and womb, with occasional black vomit, but hemorrhages, as a rule, insignificant.
Often fatal.	Proverbially non-fatal.
One attack protects from another.	One attack not protective against another.
Not protective against dengue.	Not protective against yellow fever.

Quoting Sternberg again from his article in *Buck's Reference Handbook*, Vol. VIII, page 60, speaking of the diagnosis of yellow fever, says: "Of the three prominent features making up the clinical tableau of yellow fever, viz., a yellow skin, highly albuminous urine and black vomit, only one is a constant character which can serve in establishing the diagnosis in mild cases; this is the presence of albumin in the urine. At some period in the disease, even in the

mildest cases there will be a distinct trace of albumin in the urine as shown by the usual tests, and this will be usually sufficiently abundant to leave no doubt in the mind of the observer as to the nature of the precipitate. The value of this test in the differential diagnosis is indisputable. It is true that a trace of albumin is sometimes found in the urine of severe cases of fevers of malarial origin, but in cases of yellow fever of equal severity as compared with these, the precipitate would, as a rule, be very abundant on the third or fourth day of sickness, forming a deposit to the extent of one-fourth to one-half of the contents of the test tube, or even more. At the same time a microscopic examination would show the presence in the urine of numerous granular casts from the tubuli uriniferi. These are found also, although in a smaller number, in the urine of the milder cases during the second stage of the disease."

"The second stage of the disease is commonly, however, well marked in non-fatal cases, and is its most characteristic feature, the remarkably slow and soft pulse, the evident prostration of the vital powers, although the patient may be comfortable, and even cheerful and desirous of getting up and taking food, the yellow tinge of conjunctivæ and skin (not always present), the tenderness on pressure in the epigastric region, and often a feeling of weight and distress, attended with intense thirst and vomiting of a transparent acid fluid, or of the characteristic black vomit, the tendency to passive hemorrhages from the mucous surface of the mouth or nose, oozing of dark blood from the gums or lips, or sides of the red and fissured tongue; the scanty urinary secretion, and the presence of albumin, usually in considerable amount, constitutes an unmistakable ensemble of symptoms."

It appears from the above quotations that the symptoms which have heretofore been relied upon to differentiate between yellow fever and dengue are the occurrence in the former of albuminuria, the characteristic facies (inclusive of jaundice), the divergent pulse and temperature, excessive irritability of the stomach, and increased disposition to hemorrhages. The absence of such symptoms in the main, the presence of an eruption in a large proportion of cases, and a want of mortality are characteristic of dengue. In the epidemic herein described we have an apparently inextricable confusion. A wide spread epidemic of fever presenting the symptomatology of yellow fever in many instances, but with the eruption of dengue and practically with no mortality. One of two deductions is irresistible, either the two diseases approximate more intimately in their symptomatology than has heretofore been taught or yellow fever of remarkably mild type has been associated to a greater or less degree with dengue; granting the reliability of the testimony herein presented both conclusions are warrantable. I shall not attempt here to solve this problem so far as the epidemic of the interior is concerned, but will present the evidence which is convincing to my mind that the latter proposition is true as to the coast cities of Galveston and Houston. Before doing so however, let me refer briefly to certain facts in regard to the epidemic east of the Mississippi taken chiefly from the report of the Louisiana State Board of Health, dated Dec. 6, 1897. The first death from yellow fever was reported by Dr. J. M. Holloway of Louisville, Ky., about August 18, the patient having gone to that city from New Orleans via Ocean Springs where the disease was supposed to have been

contracted. Subsequently to which, four official investigations were made as to the nature of the epidemic at Ocean Springs resulting as follows:

1. The visit of Dr. S. R. Oliphant, president of the Louisiana Board of Health August 22, 1897, who reports finding an epidemic had been prevailing the previous six weeks, that 400 cases had occurred in the practice of two physicians, without a single resultant death, and that it was considered to be dengue of mild type.

2. On August 23 a commission of experts from the New Orleans Board, from the Mississippi State Board and others sign a report which concludes as follows: "After a careful inspection and examination of the aforesaid cases, we are positive in our opinion that the disease is dengue, and that in no case is there or has there been any symptoms which would lead to even a suspicion of a more serious disease."

3. On August 27, we have a report of another commission, to which the name of the health officer of Alabama is added, stating: "In reply to your request we have again investigated the fever at Ocean Springs, which is abating and absolutely without fatality. The conclusion arrived at was that it is not yellow fever."

4. On September 6, we have the following statement: "The patient died Sunday night, and early Monday morning the expected autopsy was performed by the bacteriologist of the board in the presence of the medical gentlemen assembled. Unmistakable evidences of yellow fever having been revealed, we arrived at a unanimous verdict."

According to Dr. Oliphant the grand total of cases in New Orleans did not reach 2000, nor the deaths 300, a mortality of 15 per cent. based upon reported cases which would doubtless be much smaller if founded upon the actual number. Another significant fact noted by Dr. Oliphant in the epidemic, which verifies the history of previous ones in New Orleans and elsewhere, is that yellow fever does not burst forth suddenly, but gathers volume and force after smoldering for a time, e.g. it was introduced into Edwards, Miss., August 8, but gained no headway until the middle of September. Confirmatory as to the remarkable mildness of the last epidemic¹ Dr. L. Sexton writes from New Orleans September 20, "*Our present death rate is lower than in any epidemic of yellow fever*, if the present death rate prevails throughout this visitation we will have to send around a subscription list for our undertakers."

What bearing have these facts upon conditions as they existed in Texas? In my opinion they are convincing when taken in connection with the clinical history of certain cases that the epidemic upon the Texas Gulf Coast was similar to that in Louisiana, Mississippi and Alabama, the results being modified by the late introduction of yellow fever infection and by the presence of unfavorable conditions for its dissemination. It should be remembered that the declaration of quarantine by Galveston was made on September 10, nearly a month after the recognition of yellow fever at Ocean Springs, that the latter place is directly upon a common route of travel between eastern and Texas points, and that a month subsequently the diagnosis of yellow fever in Galveston and Houston was made by Dr. Guiteras. Under such circumstances it is not surprising that yellow fever infection should have been introduced into Texas; nor should it be a matter of wonderment that it should not have

¹ American Medico-Surg. Bulletin, Oct. 10, 1897, page 908.

Observer and location.	Date of outbreak; proportion of population affected; duration; origin.	Meteorologic and hygienic conditions.	Symptomatology.
Dr. C. H. Wilkinson, Galveston, Southern coast. Pop. about 50,000; treated 500 cases. "History of dengue epidemic in Galveston in 1897."	July 15; commenced in light form; suddenly, August 15, becoming more virulent and spreading rapidly; 50 per cent. of population affected.	Weather excessively hot and dry. Sanitary condition said to be good.	Eruption military, coming within 48 hours, appearing especially upon face and upper part of the body, profuse perspiration. Fever of one paroxysm lasting 3 to 4 days, declining by lysis. Glandular involvement not noted. Hemorrhages frequent, especially from the nose, also from stomach and bowels. Nausea and vomiting noted, especially after Oct. 1. Many specimens of urine examined; high specific gravity; albumin absent.
Dr. Geo. H. Lee, Galveston, has notes on 490 cases. From article "Dengue or yellow fever." Reprint from N. O. Med. and Surgical Journal.	First case observed July 29, from San Antonio. Subsided latter part of November. Probably spreading from San Antonio.	Not noted.	Eruption occurred in two stages, first day hyperemia; in 80 per cent. a mild macular dermatitis coming on second to fourth day, ending in slight exfoliation. Affection of glands noted in but few cases. Hemorrhages in about 10 per cent., from nose, gums, throat, uterus, bowels and stomach one case, kidneys three cases. Albumin examined for in about 50 cases, 8 of which had previous kidney trouble; 20 out of the 42 had albumin on third and fourth day; in 6 in large amounts. Other characteristics and uremic symptoms not noted.
Dr. J. M. Coble, Dallas, D. Co., about 200 m. n. of Houston, R. R. center. Pop. about 50,000.	Date of first case September 22; spread rapidly to various parts of the city, affecting c. 6 per cent. of the pop. Arrested by cold weather November 1.	Weather continued warm until Nov. 1. Local hygienic conditions poor in some sections.	Eruption noted as slight in about 4 per cent. Submaxillary glands enlarged in about 20 per cent. Hemorrhages not noted, neither dysenteric symptoms; urine examined in 25 per cent. and slight albuminuria found in 10 per cent. of these; slight nausea in a number.
Dr. Frank Paschal, San Antonio, Bexar Co., S. W. Tex.; c. 150 miles from coast; elevation c. 1000 ft.; pop. c. 5000.	Outbreak began Aug. 1; spread rapidly, soon affecting 75 per cent. of the pop. Lasted until about Oct. 20. Possibly introduced by attendants upon the interstate drill July 19-26.	Weather excessively hot and dry. Sanitary condition very bad; no sewerage; San Antonio River polluted, stinking.	Eruption present in possibly 90 per cent., coming on at end of the fever, erythematous. Hemorrhages and glandular involvement not noted. Nausea and vomiting frequent and severe; present in 33 1/4 per cent. No dysenteric symptoms noted. Albumin not examined for. No uremic symptom noted.
Dr. W. L. Peeples, Navasota, Grimes County, about 70 miles north of Houston. Population, 5000.	Outbreak about September 1, attacking negroes only until middle of the month, when it spread to all classes and ages, affecting probably 50 per cent. of the population.	Nothing noted.	Attack sudden, high fever, low pulse, severe epigastric pains, excruciating pains in back, head and extremities, the latter less severe. Nausea and vomiting incessant. Eruptions frequently absent in adults, almost invariably present in children. Glandular enlargements frequent in the neck and surrounding regions; hemorrhages quite frequent from gums, stomach, nose, bowels, uterine appendages and kidneys. No dysenteric symptoms in reality. Albumin, from slight trace to abundance in urine, with almost total suppression (readily yielding to proper diuretic treatment), varying from a deep straw to blood color, no casts and frequent uremic symptoms. Prognosis always favorable (comparatively speaking). Albuminuria does not deter prompt recovery, according to my experience.
Dr. R. R. Walker, Paris, Lamar Co., near N. E. border. Pop. c. 10,000.	Epidemic slight; began in July and continued until frost.	Nothing unusual noted.	Eruption present in but a small percentage, reddish papules appearing first upon face and exposed surfaces. Glandular involvement and hemorrhages not noted. No symptoms of dysentery. Albumin present in 25 per cent. of the cases; nausea and vomiting in 50 per cent.
Dr. Geo. R. Taber, Bryan, Brazos Co., c. 100 miles N.W. from Houston; population c. 4000.	First case reported Oct. 10, a Polander, having been exposed a week previously in Houston. The second case, a German, also from Houston. A week later a dozen cases and in the next thirty days about 100. The disease disappeared upon the advent of cold weather.	Weather dry, not excessively hot; hygienic conditions good.	Eruption present in 50 per cent., scarlatinaform and urticarial glands involved in two cases only, cervical. Hemorrhages, percentage small, in one case resembled black vomit; coagulated blood in stools in this case. Nausea and vomiting severe in most cases, with excruciating headache. Albumin was examined for in only two cases and not found.
Dr. Taylor Hudson, Belton, Bell Co., c. 150 miles N.E. from Houston and San Antonio; population 5000.	Began about September 1, spread to all parts of the town in twenty days, affecting 60 per cent. of the population. No evidence as to origin.	Nothing unusual as to weather; hygienic conditions of the town good.	Eruption not described, present in 50 per cent.; glands not often involved; hemorrhages noted occasionally from the nose and uterus; nausea and vomiting in 80 per cent., and in 20 per cent. severe; dysenteric symptoms rare; albumin only tested for in a few suspicious cases and found in several; urine diminished, dark color, no blood noted; uremic symptoms pronounced in several cases.
Drs. Wilson, Harris and Young, Navasota, Grimes Co., c. 70 miles N.W. from Houston; population c. 5000.	Epidemic began about September 15, affecting about 75 per cent. of population; rapid spread; declined about December 15; no evidence as to origin.	Weather dry, no unusual heat; local hygienic conditions good.	Only a few examinations for albumin made, none found; no uremic symptoms noted. Eruption present in about 25 per cent., resembling that of scarlatina and measles, at times confined to face and neck. Cervical glands and tonsils enlarged, as a rule, in cases with rash. Hemorrhages from nose, uterus, bowels, gums and kidneys occurred frequently. Nausea and vomiting in about 80 per cent., often obstinate and severe. Albuminuria examined only toward close of epidemic in about 50 cases, present in 40 in good quantity; diminished quantity and high colored urine, casts and blood cells in 3 cases; uremic symptoms in 4.
Dr. Thos. G. Duncan, Victoria, Victoria Co., c. 125 miles S.W. from Galveston and Houston, near coast; population c. 2500.	Epidemic began about September 15, affecting about 33 1/4 per cent. of population in town and smaller proportion in the country. No evidence as to origin.	Weather dry and hot, but not unusually so; haziness of atmosphere was noted similar to that of 1867.	Eruption in part of cases erythematous. Glandular involvement not noted. Heard of one case of black vomit; nausea marked and almost universal; dysenteric symptoms not noted; no urinary symptoms noted.
Dr. E. W. Link, Palestine, Anderson Co., c. 150 miles north of Houston; railroad center.	Epidemic commenced about middle of September; spread rapidly, affecting about two-thirds of the population. Probable origin San Antonio and Houston.	Weather hot and dry; local hygienic conditions bad.	Measly eruptions generally present; enlarged glands not noted; hemorrhages in a few cases from nose and bowels; nausea and vomiting not noted often; dysenteric symptoms in a few cases; albuminuria and other urinary symptoms not examined for.
Dr. W. W. Walker, Schulenberg, Fayette County, about midway between San Antonio and Houston. Population about 1500.	First case August 19, 90 per cent. of population attacked, declined about Oct. 10 for want of material, then spread to the country and continued until Dec. 10.	Weather dry, little wind, temperature reaching 102 degrees in shade. Local hygiene good.	Eruption present in 90 per cent., irregular as to time of appearance and character. Glandular involvement noted in about 4 per cent., especially in children, parotid, sublingual, inguinal, suboccipital. Suppuration in two cases. Hemorrhages occurred in about 4 per cent. from the nose, gums, rectum, in one generally from mucous membranes, in three cases black vomit. Stomach, nausea and vomiting almost universal. Severe dysenteric symptoms in a few cases. Albumin tested for only in worst cases and found in about ten, in some in large amounts.
Dr. J. W. Thomason, Huntsville, Walker County, about 70 miles north of Houston. Population about 2500.	Sept. 21, first case a young lady from Galveston, it was several weeks before other cases occurred in the same house though it was full of young ladies. Other foci of infection were developed by parties from Houston and Galveston, rapid spread after above date. About two-thirds of the population affected. Duration of epidemic about three months.	Weather excessively hot and dry, no other form of sickness prevailing.	Eruption present in 2% of cases; erythematous, military, scarlatinaform and rubeloid. Glandular enlargements not noted. Hemorrhages, out of 180 cases three had bleeding from stomach, in one the case from Galveston resembling black vomit. Nausea and vomiting present in nearly every case, distressing in many. Mild dysenteric symptoms noted in about 7 per cent. Abdominal pains in region of appendix noted frequently.

Ratio of pulse to temperature.	Jaundice.	Mortality.	Progressive severity.	Remarks.
Pulse rate comparatively slow and regular, many cases not above 84 or 100 with temperature 103.	Began to be observed in a large proportion of the cases after Oct. 1. in most cases confined to conjunctivæ, in others upon face and coming on early in the fever.	Does not believe there was a case of yellow fever in Galveston. The Wade case was the most suspicious. Diagnosis, <i>acute infectious jaundice</i> . Death certificate signed uremia.	Distinctly noted; mild in the beginning, latter part of July and August. More severe in September and still more virulent in October.	Conclusion. The Wade case was not yellow fever because of survival beyond usual duration, intense nausea and protracted retching instead of easy vomiting; calm indifference to surroundings, lack of postmortem evidence of fatty degeneration of kidneys or liver and of hemorrhages.
Want of correlation between pulse and temp. occurred so frequently as to be almost the rule, <i>e. g.</i> , temp. 102.3, pulse 66; temp. 103, pulse 80. This condition noted in some from beginning and in others after second paroxysm.	Jaundice of mild grade was the rule from first to last, not of the skin, for this was noticeable slightly in a very few, but a slight yellowness of the conjunctivæ.	Practically no mortality; one death in which dengue occurred as a complication of a previously existing interstitial nephritis. Does not believe there was any yellow fever in Galveston during the past season.	Not specially noted.	Temp. usually high in beginning, came (after slight remission) high again toward end of attack. Duration on average, 4 days; in mild cases 3, in 50% 5. Conjunctivæ usually mildly injected. Also hyperemia of face and neck. Neuralgic symptoms marked in 90% of cases in head, back and limbs.
Not noted.	Marked and noted in 30 per cent.	No deaths. Suspected yellow fever at first owing to jaundice, nausea and vomiting and temperature.	No difference in severity as epidemic progressed.	
Abnormally slow.	Not noted.	No mortality. Yellow fever not suspected.	Increased.	
Generally abnormally slow in proportion to height of temperature, <i>e. g.</i> , pulse 45, temperature 100; pulse 80, temperature, 105.5.	More or less present.	No mortality. Recognized analogous symptoms, but did not suspect yellow fever.	Very little difference in severity as the epidemic progressed.	Continued during January, 1898. Noticed several sequelæ, one of them falling of the hair during second and third months after recovery.
Normal.	None noted.	None.	But little difference.	
Pulse about 120, with temperature 103-105	None noted.	No deaths. Not suspected.	No increase in severity as epidemic progressed.	Small number of cases ascribed to extraordinary sanitary precautions and strict quarantine.
About normal.	Mild in 10 per cent., severe in 2.5 per cent.	One death from uremic complications; case seen in consultation; no autopsy. No.	No difference.	
In 50 per cent. cases abnormally slow pulse in proportion to temperature.	Jaundice in 75 per cent. more or less marked.	No deaths. Suspected from symptoms, but lack of mortality precluded such an opinion.	No marked difference as epidemic progressed.	More severe with old people; children suffered comparatively little.
Not noted.	Found in a few cases.	No mortality in the absence of complications. The case of suspected death from yellow fever turned out otherwise. No.	Decrease in severity as epidemic progressed.	
Not noted.	Noted in a few cases where nausea was marked and hard to control.	Two deaths, one with uremic symptoms and one from bowel complications. Is not sure they died from dengue; occurred in the practice of Dr. Evans. No.	Not noted.	
Abnormal slowness of pulse in proportion to temperature. In one case pulse 72, temperature 102½. In another, pulse 90-96, temperature 103-104.	Observed in 4 per cent., to a slight degree in about 7 per cent.	Lost but one case, which was complicated by acute rheumatism and mal-assimilation. Only one other death from dengue, but a number of old persons have died during following winter from failure to recuperate. Symptoms of some cases so nearly approached those of yellow fever, unable to discriminate.	Epidemic increased in severity for about six weeks or until it subsided for want of material.	Dr. Walker is familiar with both yellow fever and dengue.
Pulse slow in proportion to height of temperature. In one case pulse 72, temperature 102½. In another, pulse 90-96, temperature 103-104.	Jaundice noted in about 7 per cent. Gastro-duodenal catarrh to some extent in most cases.	No mortality. No.	Worst cases in beginning and middle of the epidemic.	

Observer and Location.	Date of outbreak; proportion of population affected; duration, origin.	Meteorologic and hygienic influences.	Symptomatology.	Remarks.
Dr. Robert T. Morris, Houston, Harris Co., fifty miles from coast, railroad center; population about 50,000.	About September 1; mild at first, rapidly spreading in three weeks, affecting a large proportion of the population.	Not noted.	Paroxysm—Single. Temperature—Rises regularly. Duration—Three to five days. Tongue—White center, red pointed. Conjunctiva—Injected. Stomach—Irritable and nausea. Vomit—Frequent. Neuralgic signs—pain in head, back and stomach. Eruption—Erythema noticeable. Jaundice—Frequent, especially in conjunctivæ. Secretions—Deficient. Urine—Diminished, albuminous. Hemorrhage—Frequent and alarming, black vomit. Mortality—About thirty deaths. Pulse—Divergent pulse and temperature frequent.	In the January, 1898 number of the S. W. Med. Record Dr. Morris discusses the nature of the epidemic in Houston; from this article the following is a condensed statement. He shows: 1, how infection may have occurred by refugees from Ocean Springs before quarantine was declared; 2, that the cardinal symptoms of yellow fever were present in many cases, viz., the characteristic fever, divergent pulse and temperature, jaundice, scanty suppressed and albuminous urine, black vomit in three cases; a connecting link was noted between anomalous cases in several instances. An increase in the mortality rate of 20 over that of the preceding year was noted; 11 deaths ascribed to senility, 5 from dengue, 11 from enteritis and gastritis, 10 from fever, 1 from meningitis and 5 from kidney diseases.

been generally recognized when we take into consideration that it came in the guise of dengue, was introduced late in the season, into localities where the conditions were unfavorable for its spread, and that according to all testimony, it was the mildest epidemic of yellow fever ever known in the history of the country.

Admitting that there is greater similarity in the symptomatology of the two diseases than has heretofore been acknowledged, the question arises, how can they be differentiated? In my opinion chiefly by the symptom complex of an acute nephritis in yellow fever and its absence in dengue. In the latter, simple parenchymatous changes may occur in the kidneys and be manifested by an evanescent and mild albuminuria. While in the former in a series of cases many will afford incontestible evidence of the occurrence of a severe nephritis, viz., scanty urine, of high color and specific gravity, intense and persistent albuminuria, hematuria, casts, decided tendency to suppression and the accompanying uremia.

The following are brief clinical histories of the three cases, reported by Dr. R. T. Morris occurring in Houston² and one from Galveston reported by the writer.

Case 1.—Oct. 23, N. J., aged 28, was called late in the evening; found patient suffering with anorexia, pain all over body, but especially marked below knees; constipated but urinating freely; temperature 103; severe frontal headache; no albumin in urine. Prescribed castor oil, and being called out of the city, did not see patient till three days later, when he was found to be very low; pulse hardly perceptible, not over fifty-four to the minute; retching but no vomiting; urine heavily loaded with albumin; total amount voided in twenty-four hours three pints; patient muttering to himself, but on speaking loud to him could be aroused, and would give intelligent answer, although a few minutes after conversation ceased he would drop back to unconsciousness; at 6 P.M. vomiting of a coffee-ground-like substance set in, not more than a tablespoonful every hour till next morning, when, of a sudden, without any effort whatever, a gush of same kind of vomit was ejected, amounting to at least a pint and a half. Inside of fifteen minutes after this vomit patient expired, and after ten minutes his corpse was of a decidedly yellow tinge, and dependent portions discolored like after severe bruising.

Case 2.—September 19, called to see I. R. F., male, aged 22, found what I believed to be incipient dengue; reported improved by the 21st; on the 22d recalled in haste; on arrival found patient comatose, pulse 56, temperature 103.5 degrees; on arousing he told me, and the statement was confirmed by his mother, that all urine he had passed since the day before (in all 28 hours) was in a vessel under the bed. By ocular inspection was found to be very dark and muddy, smell strongly ammoniacal, examined at office, albumin in great quantity, nearly solidifying in test tube. Returned at once to patient; found him again in comatose condition and having voided a small quantity of urine which had strongly colored the linen. Prescribed tincture digitalis, ergot, spirits juniper and liquor ammoniac acetatis. Recovery uneventful but exceedingly slow; yellow tinge in eye appeared as late as 26th, disappearing after forty eight hours.

Case 3.—R. T. Jr., native of Galveston, aged 16, of robust constitution and previous perfect health, was taken sick suddenly October 24 in the afternoon, with a slight chill followed by high fever, with intense headache, pains in the back, limbs and joints. At my first visit on the 25th, as soon as the room was entered a peculiar nauseating odor was perceived, the eyes were watery and red with a yellowish tinge, the skin was decidedly yellow, the gums were softened and disposed slightly to bleed, anorexia was marked, tongue coated and red at its tip and edges, excessive nausea and disposition to vomit everything swallowed, bowels had moved from a purgative. The patient was nervous and indisposed to sleep. The course of the fever is typical and is exhibited in the accompanying chart. It should be noted that when a normal temperature was reached on the 28th, the fifth day of the fever, that the pulse dropped to 64, and that on the 30th when the temperature was subnormal the pulse was 50. The stomach continued to be irritable, there was epigastric tenderness. On the night of the 29th blood was vomited in small quantity; the urine was scanty, of high color and specific gravity. A heavy precipitate of albumin was found on the 29th, also granular casts. Daily examinations showed albuminuria during the following eight days, after which it gradually subsided as the urine became paler and more abundant. The albuminuria was more intense during the stage of depression. After a tedious convalescence recovery ensued. My diagnosis of a severe attack of yellow fever was confirmed by Drs. McLaughlin and Magruder, both of whom have had experience with this disease.

It is useless to add any comments or summarize any

other cases with similar histories. What other diagnosis could have been made than that of yellow fever. *Anomalous dengue* was one of the names suggested during the recent epidemic; if this is dengue, then the identity of that disease and yellow fever is established. When pressed for a diagnosis in certain of these cases, some of the Galveston experts denominated them Weil's disease, or acute infectious jaundice, which is manifestly such a far fetched conclusion that words would be wasted in its refutation.

One of the arguments which has been repeatedly used against the existence of yellow fever in Texas during the past season, was the want of mortality. Upon this point let me quote Dr. Morris again:³ "From Oct. 1, 1897 to Nov. 18, the death rate in Houston was 33½ per cent. greater than in the corresponding period of 1896." The causes given in death certificates are as follows: senility 11 (four of whom were not over 60); dengue 5; enteritis and gastritis 11; fever 10; meningitis 1; kidney disease 5. The record of Galveston does not show any increase of deaths during the months of August, September and October over the previous three years. There were five deaths however preceded by symptoms of yellow fever; it is a significant circumstance that in four of these uremia was given in the certificate as causes of death. In the other, congestion of the lungs was mentioned as the primary, and bilious fever as the remote cause.

Those who deny the existence of yellow fever in Texas during the past season rely chiefly upon the apparent indisposition of the disease to spread from numerous foci. In other words, they contend that the presence of the infection necessarily involves its dissemination. No extended argument is requisite to demonstrate the fallacy of such conclusions. The pathogenic micro-organism of yellow fever is a facultative parasite, but its ordinary mode of life is saprophytic. It grows and develops outside of the body when the conditions are favorable for its reproduction. The seed may fall by the wayside, or upon a rock, or among thorns and wither away, or upon good ground and spring up and bear a hundred fold. The fact that the soil of Texas was an unfavorable one for the multiplication of the yellow fever germ last season is an adequate explanation of the history of the recent epidemic. It is not contended that the hygienic condition in these cities was perfect, but that the combination of circumstances was antagonistic to the extensive dispersion of the infection. Instead of being a blot upon the sanitary escutcheon of Houston and Galveston, it is another demonstration of the fact which has previously been observed, that yellow fever may be brought to these places without necessarily involving an extensive epidemic or serious mortality. Two important lessons should be emphasized; 1, the urgency of promptly recognizing the early cases and calling them by their proper name, for by this means only may subsequent disaster in many instances be averted; 2, we should put our houses in order, in other words adopt every possible method of domiciliary and municipal cleanliness. Napoleon is said to have remarked that "Providence was on the side with the strongest artillery." When yellow fever is around Providence is on the side of the town with the best system of sewers. Again, it has been demonstrated that yellow fever may masquerade in the garb of dengue and that the latter is a portable disease: leaving out of the case the probable association with yellow

low fever, it became a serious question whether dengue should not be considered a quarantinable disease. The suffering and expense incident to an extensive epidemic like the one of last season would certainly appear to justify measures of prevention.

DISCUSSION.

Dr. KINYOUN of the U. S. Marine-Hospital Service—I have had some experience with yellow fever and dengue. Dr. West's paper is a very able one and he has gone into the points in differential diagnosis very thoroughly. I recall the history of the epidemic of dengue which occurred last year, April 12. The crucial test was made. In certain cities, not purposely but as a matter of convenience, persons were employed as disinfectors who had had dengue previously; none of these had the fever. Catarrhal jaundice, dengue and mild yellow fever are unfortunately closely allied. And when we take this fact into consideration in the epidemic of last year it will be known that many cases of dengue were reported which were not dengue at all but mild cases of yellow fever.

Dr. BREWER of Texas—Jaundice occurs in about 50 per cent. of the cases. There were 600 cases and there were no deaths attributable to dengue fever. There was great excitement in the whole country but when it was found that there were no deaths following this epidemic, the excitement abated.

H. A. WEST of Galveston, Texas—I regret, Mr. Chairman, that this subject has not been discussed more fully, as the situation in Texas, imperfectly sketched in the paper, was of the most interesting a medical man is ever called upon to encounter. I would like very much to have heard the opinion of those whose experience has been wider than mine, especially as the narrated facts appear to controvert the generally accepted views as to the differential diagnosis of the fevers under consideration. The diagnosis of yellow fever in Galveston and Houston made by Dr. Guiteras was fought to a finish by the public prints, the people at large and by the majority of the physicians. It was iterated and reiterated that "yellow fever kills," "there is no such thing as mild yellow fever" and woe betide the man who had the temerity to raise his voice against the verity of this assumption. The actual mortality was hidden by certificates giving as the causes of death "senility, dengue, uremia, bilious fever, etc." The argument was sophistically presented by some as in the title of a paper upon the subject, "Dengue or Yellow Fever," that is to say it must be one thing or the other and leaving out of view entirely the probability of the concurrent prevalence of the two diseases. I have presented the facts, which are conclusive to my mind, that such was the case, also that yellow fever is not always and necessarily attended by a terrible mortality (this is one of the most instructive lessons of the recent epidemic, not only as to Texas, but in the regions east of the Mississippi); that it may not rapidly spread from numerous foci; that the symptomatology of yellow fever and dengue approaches more intimately than has hitherto been taught; and that in the light of the facts I have presented, the differential diagnosis of these fevers will have to be rewritten.

RARE CASES OF ARHYTHMIA.

Presented in the Section on Practice of Medicine at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY JAMES M. ANDERS, M.D., Ph.D., LL.D.

Professor of the Practice of Medicine and of Clinical Medicine in the Medico-Chirurgical College, Philadelphia; Attending Physician to the Medico-Chirurgical and Samaritan Hospitals, etc. PHILADELPHIA, PA.

Arhythmia is a symptom that is common to many diseases and conditions, but the scope of the present article is limited principally to the clinical features of certain forms of the disorder not hitherto described, that have fallen under my observation. The examples that I shall adduce are too few to establish tenable hypotheses, either in their etiologic or clinico-pathologic bearings, yet they present points of rare clinical interest.

The first case occurred in the person of a physician, aged 40 years, who had been an abuser of tobacco for a protracted period, having habitually smoked from eight to twelve cigars daily. The family history gave undubitable evidence of a gouty tendency, and the

³ S. W. Med. Record, January, pp. 413-414.

patient himself had suffered from acute articular rheumatism on two different occasions. A careful physical examination permitted the positive exclusion of organic valvular diseases, and the probable elimination of other structural affections of the heart. Nor were any of the usual causative morbid conditions that usually precede or are found associated with arrhythmia present, except the tobacco-habit.

The functional disturbance of the heart first assumed the form of true palpitation—i.e., the patient perceived the rapid cardiac pulsations, at the same time experiencing considerable mental anxiety and slight anginous pains. A little later a curious, and so far as I know, peculiar form of arrhythmia manifested itself. For example, on auscultation four sounds could be distinguished during cardiac rhythm, and it seemed clear that both the first and second sounds of the heart were reduplicated. The fact that the first sound was doubled was confirmed by the pulse, which was felt during the auscultation of the heart; the pulse-wave appeared to strike the palpating finger at the wrist synchronously with the second (feebler) element of the systole, while the impulse at the apex coincided with the first (stronger) element of the first sound. The pulse showed the modified double beat (*pulsus bisferiens*) when moderate pressure was made upon the radial. The *pulsus bisferiens* has been most frequently met with in combined aortic incompetency and aortic stenosis. The case here recorded is the only one (apart from a double aortic lesion) in my experience in which this form of pulse was typically shown. It is doubtless dependent upon double ventricular contraction. Elevation of both arms, so as to increase the force of the blood stream in the direction of the left ventricle, increased somewhat the irregularity, and accentuated the distinctive arrhythmic features above described.

Broadbent¹ points out, also that "The *pulsus bisferiens* can not uncommonly be induced by an effort, which throws additional work upon the heart; for instance, in one case it was not present while the patient lay quietly in bed, but was brought out when he held up both his hands."

Cardiac action, in my case, was accelerated, the radial pulse ranging from 100 to 108 per minute. In a general way, the heart sounds resembled those of the well known canter rhythm, in which there is an interpolated sound, due in a majority of cases to the splitting up of the second sound, but in the instance under consideration, a second interpolated sound was heard, following immediately upon the impulse, and it was ascribed, as before stated, to a double systole. To clearly show that the double second sound was a genuine reduplication in this case, I would direct especial attention to the following points: first, it was most distinctly heard at the base; secondly, the two elements of the duplicated sound were separated by an exceedingly brief interval, and finally, that both strongly resembled the normal second sound.

True reduplication of the second sound, which depends upon "a disturbance of the relation which normally exists between the pulmonary and aortic pressures," results from a great variety of causes. It is a well-established fact that in conditions in which the pulmonary tension is unduly high (mitral stenosis, etc.,) doubling of the second sound is common. Arthur G. Phear² states that it may be met with in

cases of anemia and debility, conditions that were not present in my cases. Phear has made an analysis of twenty-five cases of which detailed notes were available, with the following results: "a, mitral murmurs were present in ten cases, in five of which the murmur was presystolic only, in four systolic only, and in one double; b, in twelve cases, exclusive of the ten with mitral murmurs, anemia or debility was present, the individuals in many instances being convalescent from some acute febrile disease; c, two cases of acute lobar pneumonia, and d, in one case there was hypertrophy of the heart, with high tension pulse, and 'bruit de galop' audible at the apex."³

I have carefully excluded so-called simulated reduplication, which is audible at the apex only, while at the base a single second sound is heard. Simulated reduplication, a rare condition, can not for lack of time and space be further considered here. A sphygmogram could not be conveniently obtained.

The patient was strongly advised to discontinue the smoking habit, and at his next visit, one month later, the peculiar form of arrhythmia, to which the term "double reduplication" of the cardiac sounds might be appropriately applied, had practically disappeared. Since then mild attacks of palpitation at long intervals, particularly as is usual on assuming recumbent posture at night and an occasional intermittences have been experienced.

A second instance of so-called "double reduplication" was observed in a female, under my charge in the Medico-Chirurgical Hospital, aged 43, single, suffering from exophthalmic goiter in the advanced stage. The latter affection followed prolonged physical and mental strain. All of the characteristic symptoms had apparently developed in their usual sequence, i.e., tachycardia, muscular tremor, exophthalmos, and lastly, thyroidean enlargement. The cardiac impulse at the time of my first examination was greatly exaggerated; percussion dullness increased slightly, both to the right and the left, and auscultation rendered audible a blowing murmur over the base of the heart, while the valvular sounds were accentuated.

There was probably slight cardiac dilatation (secondary to functional hypertrophy) present, a common incident in this disease. The case immediately prior to admission (February 28) had, as stated before, reached an advanced period, with constant and markedly irregular action of the heart (*delirium cordis*). Twenty-four hours before death a gallop rhythm was clearly distinguishable on auscultation, while twelve hours previous to death, or at my last examination of the case, both the first and second sounds were apparently reduplicated. In this instance, also, the pulse was felt at the same time that auscultation was practiced. The *pulsus bisferiens* was not present. The reduplication in this instance, as is usual, was most clearly heard when the stethoscope was placed partly over the left and partly over the right ventricle near to the apex-beat. It was obviously caused by asynchronous contraction of the two ventricles.

A third case of arrhythmia, while manifesting distinctly peculiar and rare features, was associated, as commonly occurs, with marked obesity. M. W., aged 58 years, widow, childless, weight 280 pounds, complexion ruddy, consulted me August 10, 1896, on account of inordinate dyspnea on slight exertion, and gastric disturbance. The family history was negative, except-

¹ Heart Diseases; With Special Reference to Prognosis and Treatment, p. 143.

² Lancet, January 9, 1897.

³ Loc. cit.

ing the presence of positive evidence of a slight gouty taint. The patient had begun to take on flesh in a slow and gradual manner twenty years previously, though actual lipomatosis had not existed for more than ten years.

Condition at the time of examination.—The pulse was found to be wholly irregular, both in volume and rhythm, and increased in frequency to an average rate of 96 while the patient was at rest. On auscultating the heart while the pulse was felt at the wrist, it was noted that systole occasionally failed to send a pulse-wave to the radial that the palpating finger could detect. Upon careful and repeated physical examination, which although far from satisfactory in its practical results on account of the enormous deposits of fat, valvular affections of the heart were not demonstrable. On the other hand, apart from the arrhythmia noted before, nothing but the evidences of marked obesity and a feeble, muffled cardiac first sound were present.

As stated above, the condition at the time I first examined the case took the form of "combined arrhythmia," i. e., irregularity in both volume and rhythm. Shortly after, a typical "pulsus alternans" was occasionally noted. Recently, while the patient was suffering from an attack of influenza, I observed the "pulsus alternans" along with a modification of the rhythm that suggested an analogy to the Cheyne-Stokes type of breathing. For example, after a comparatively short pause, or an intermittence, both the pulse and heart beat would begin at a slow rate and gradually increase in frequency for from eight to ten beats, at which moment the heart action would be quite rapid, to be followed by a second, abrupt pause, and so on.

There was present at the time the signs of a dry form of bronchitis (cough and sibilant râles on auscultation), with slow, asthmatic breathing superadded. The periods of exacerbation or increasing acceleration of the cardiac contractions coincided, in the main, with the latter part of the inspiratory element of the respirations, while the pause following was synchronous with expiration. The remarkable influence of the respiratory function upon the cardiac action was further shown by the fact that during the held breath the heart rhythm at times became almost regular, at others it merely manifested decided improvement. I had previously witnessed occasional intermittence and the "pulsus alternans" in *morbis adiposis*, but not the peculiar form of pulse or cyclical increase in the rate noted in this instance. Kisch⁴ contends that the "twin pulse" and obesity are conditions frequently found in association.

In the not infrequent irregularity of the cardiac action met with in the obese, an affection of which this case is a well marked example, I am inclined to believe that the condition is in great part dependent upon mechanical interference with the movements of the heart. That this embarrassment, however, is not wholly attributable to the depositions of fat, but partly to the respirations acting upon a heart already enfeebled by the toxins of influenza, is shown by the effect of a suspension of the latter function in the case reported above. Nothnagel⁵ has emphasized the fact that in meningitis the pulse may vary from minute to minute, the slow pulse, as in my own case, may

suddenly increase greatly in rapidity, and again become retarded. Baumgarten⁶ holds that these sudden oscillations are dependent solely upon central irritation. In the case reported here, however, the rise and fall of the pulse occurred almost synchronously with the respiratory acts, the variations or cycles occurred, therefore, from ten to twelve times in a minute. Again, it is a not infrequent matter of observation to find the presence of murmurs and various forms of arrhythmia whose existence is totally dependent upon the influence of the respirations. In this connection, I may state that I have observed cases in which apical systolic murmurs were audible only during the latter part of inspiration and the beginning of expiration. In one of these the murmur could be maintained for a considerable period during held inspiration. In another case, an occasional intermittence was also noted on inspiration. Neither of these two cases presented any evidences of organic or structural changes of either the heart or lungs; they both occurred, however, in neurasthenic subjects. The significance of the forms of arrhythmia that I have described can not be positively stated, but they are probably grave in cases in which the cause or causes are not readily removable, as for example in the case of exophthalmic goiter reported above that proved speedily fatal.

In conclusion, I desire to restate in sequence some of the most interesting points embodied in this paper.

1. The presence of reduplication of both first and second sounds (double reduplication) in the first two cases, one of tobacco poisoning, the other exophthalmic goiter.

2. The occurrence of a typical *pulsus bisferiens* in case one, dependent upon the toxic effect of tobacco, in the absence of combined aortic regurgitation and stenosis.

3. The presence of a cyclical increase in the rapidity of the movements of the heart, followed regularly by a brief pause; and the striking effect mechanically of the respiratory function upon this peculiar variety of arrhythmia.

4. The temporary production of apical systolic murmurs during the inspiratory element of the respiration.

5. That all of the cases developed in subjects in whom previously existing valvular lesions of the heart, so far as determined, were absent.

THE PRESENT STATUS OF VACCINE AND VACCINATION.

Presented to the Section on Practice of Medicine at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1897.

BY W. F. ELGIN, M.D.,

ASSISTANT HYGIENIC LABORATORY U. S. MARINE HOSPITAL SERVICE (A BUREAU OF THE TREASURY DEPARTMENT).

It will not be attempted in this article to go into a historical résumé of vaccination, but it may be profitable to discuss briefly the relation existing between smallpox and vaccinia. Since the beginning of this century, numerous experiments have been made to determine whether they are distinct diseases with interchangeable immunity, or whether vaccinia is an attenuated smallpox obtained by its passage through an animal of greater resistance. Gassner in 1801, Sunderland in 1828, Thiele in 1836, Ceely about the

⁴ Berliner Klinische Wochenschrift, Berlin, March 18, 1895.

⁵ Deutsche Archiv für Klinische Medizin in 1876, quoted by T. A. Clayton, University Medical Magazine, January, 1898.

⁶ Transactions of the Association of American Physicians, Vol. III, 1888.

same time, Babcock in 1840; and later experimenters such as Voight, Fischer, Haccius, Eternod, Copeman and Klein have all been able in one or more cases to produce vaccine by passing variolous material through cattle. Probably King of Madras, 1891 or 1892, has reported the most striking results, in which more than 400,000 persons were vaccinated with lymph thus produced, without reverting in any particular to its origin—smallpox. Frequently the first remove will not sufficiently attenuate the lymph, so that its inoculation in the human may produce symptoms similar to variola, as is instanced in Martin's cases, 1836; Reiter's, 1839; and Chauveau's in 1864. This may be corrected, however, by making a number of removes through animals before attempting to vaccinate the human subject. These observers, therefore, believe that the two diseases have a common origin. The most prominent modern objectors to this theory are Chauveau and Cruikshank. Chauveau, as President of the Lyons Conference, reported in 1864, that the two diseases were entirely distinct, though vaccination produced immunity from smallpox, and vice versa, by direct antagonism; in 1891 he reaffirmed his previous position, stating that "Vaccine virus never gives variola to man, nor does the virus of variola ever produce vaccinia in the ox or horse. The two viruses can not, therefore, be reduced to a single virus." Cruikshank, who with the pertinacity of an Englishman for preconceived notions, after referring to the numerous results obtained by other investigators, calmly says that they are mistaken; and that virus obtained from the variolation of cattle was not vaccine at all, but modified variola, though he is careful to give no test by which we can distinguish between the two diseases.

Copeman in 1896, after a careful review of the evidence on both sides, sums up as follows in speaking of inoculating calves with smallpox virus: "The final results, however, after greater or less number of removes from calf to calf, has been invariably the same, namely, the production of a local vesicle, indistinguishable by any means at our command such as the appearance and course thereof, or the protective power of the lymph derived therefrom, from true vaccinia."

VACCINATION FROM THE STANDPOINT OF BACTERIOLOGY.

Having determined that vaccinia is only an attenuated smallpox, it follows that the active principle must be the same in both. Numerous investigations by eminent authorities have failed to this time to prove anything definite, as to its identity. Chauveau in 1865 reported the following results of his investigations; he found vaccine lymph to be composed of a fluid part in which there were white corpuscles, and a number of granules many times smaller than the leucocytes. These constituents were separated by diffusion, and it was shown that in inoculation it was the granule alone that communicated vaccinia. But little advance has been made from this position today. Copeman in 1891 reported a series of experiments which appeared to prove that the active principle was in the solid constituents of the lymph. After filtration the liquid had no potency while the remaining solid matter produced normal vaccine vesicles. This I verified in 1895 with material filtered by Dr. Kinyoun, the animals vaccinated with the fluid after filtration showing absolutely negative results. This would seem to show the particulate nature of the virus.

Martin in 1891 (reported by Ernst in 1893), obtained a bacillus from the lymph of a vaccine vesicle, which he believed to be the infectious agent. He claimed that the ninth generation on blood serum produced a typical vesicle in the calf. He says, however, "These cultures were not pure, but contained quite a variety of bacteria; in every instance blood serum was liquified." He states that what he considers the specific agent varies in form, according to the various conditions of its nutritive environments, and consequent rate of its development. The most constant form is a short, fine bacillus, with rounded or nearly square ends. According to his own testimony, he had not isolated a specific organism.

In 1891 or 1892, Copeman, with Kent and Klein, though working independently, claimed to have found a bacillus described as follows: 1 μ in length and one-half as thick, heavily stained at ends, almost unstained in the middle, possibly spores. Found also in tissues in groups of from two or three to ten. This organism cultivated by special methods was inoculated into a calf, which on the fourth day produced a vesicle indistinguishable from that produced by vaccine. In 1896, Copeman reports still further results with this organism, describing a more or less imperfect method of cultivation. Pure culture obtained after one month's growth produced typical vesicles in a calf, which protected it from subsequent vaccination or variolation. Children were also vaccinated successfully with material taken from a calf vaccinated with this culture. I have not been able to find any further report from Copeman, but it is said that after further investigation he has abandoned this bacillus as the cause of vaccinia or smallpox.

Since Laveran's discovery as to the malarial organism, investigators have been tempted to make special examination of the blood, thinking that probably the parasite might be of an animal nature. Guarnieri and Pfeiffer have called attention to organisms in the lymph which they believed to be of the nature of a parasitic protozoon and the probable active vaccinia principle. These results seemed to warrant further investigations; and Dr. Walter Reed, U. S. A., in 1897, in an exhaustive research covering a period of five months, made a report in which he confirmed the results of Pfeiffer, in that small ameboid granular bodies in the blood of children and monkeys who had never been vaccinated, though not in such large numbers. Dr. Kinyoun's researches at the laboratory of the U. S. Marine-Hospital Service about the same time would seem to warrant similar conclusions. He found them also in animals not vaccinated. These researches would suggest that these bodies are in the normal blood and are probably increased in large numbers as the result of inflammation, and it is certainly not proven that they are the active principle of vaccinia.

As to what are termed by Copeman "extraneous bacteria," the literature on this branch of the subject is so profuse that it will only be possible to make a summary. Probably the most complete research along this line has been made by Cruikshank extending over some years. He has found in the various stocks of lymph, staphylococcus pyogenes aureus, staphylococcus pyogenes albus together with a large number of saprophytic bacteria. The streptococcus has been reported by Copeman and Whitlow. Dr. Reed examined the points from six vaccine farms and found staphylococcus albus and aureus in all the

plates. I, myself, in examining lymph at various times from several sources have almost invariably found the staphylococcus albus and aureus and frequently the streptococcus; and in one instance, finding that the vaccinations on heifers seemed to produce excessive discharge and tissue necrosis at the point of inoculation, I took cultures and found the predominant bacterium to be the streptococcus. This is simply one illustration of the importance of bacteriology to the production of vaccine lymph. Weaver, instructor of bacteriology of Rush Medical College, obtained points from four producers as sold in Chicago and in the cultures from all found pathogenic organisms. Fütterer examined seventy-five ivory points from different sources and found staphylococcus aureus in fifty-five, staphylococcus albus in about the same number and the streptococcus of erysipelas and phlegmon in ten. I have also found in numerous cultures from vaccine a short motile bacillus with rounded ends, resembling the pseudo-diphtheria in grouping, growing on ordinary media, but in bouillon producing a pellicle which falls to the bottom in flakes. This bacillus is poly-morphous, taking different forms so frequently in its cultivation as to make it difficult to prevent contamination: as most frequently found the staining is bi-polar. This organism has been noted by Dr. Carrol. I am inclined to think that it is the bacillus reported by Martin, the contamination reported by Ernst being probably the changing forms of this organism. It is pathogenic to white mice. The press of other work has precluded a further investigation, but I expect to continue it in the near future.

The finding of extraneous organisms in the lymph is so general and in such large numbers as to suggest the possibility of numerous accidents accompanying or produced by vaccination: and in fact, we all know that intensely sore arms are so frequently the result of vaccination that the laity and, in fact, some physicians suppose that there is no protection without this local necrosis and its attendant symptoms. We now know that the most of this inflammation is due to *extraneous pathogenic organisms* and is not the legitimate result of vaccination. In addition to this unnecessary local condition, numerous instances of systemic poisoning are reported which evidently are not necessary to vaccinia. Thus Fox reports cases of more or less pronounced dermatitis, also mentions the "lamentable occurrence of septicemia and pyemia," as well as the rarer complication of tetanus. Further on he says: "Erysipelas is from its frequency and gravity the most important disease in this group." And again remarks that "more or less profound ulceration and even gangrene is not a very rare sequel to vaccination." Probably the most common affection of this group is contagious impetigo. This is a benign affair, but none the less a source of grave anxiety and consternation to parents.

During the Civil War vaccination with septic lymph or crusts resulted in hospital gangrene, tetanus, pyemia, septicemia, etc.

That syphilis may be produced no one will deny when humanized lymph is used. Dr. Arning detected the bacillus lepræ in the lymph and crust of a vaccinated tubercular leper. Dr. Fox reports three cases of lupus in vaccination scars. Professor Toussant vaccinated a tuberculous calf with lymph from a healthy infant. The lymph from the pustule in the calf was inoculated into four rabbits, a pig, a cat and a pigeon:

two rabbits killed two months later displayed local glandular and pulmonary tuberculosis, a third killed on the 218th day and the fourth on the 246th day were tuberculous. I am aware of conflicting reports; yet when such results have been obtained by competent observers we can not close our eyes to the danger of tuberculosis resulting from tuberculous lymph.

We might continue indefinitely multiplying examples of accidents reported from the use of infected lymph, but this is unnecessary, as any thinking man must see that bacteria of all kinds are liable to grow in an open wound, and that the bacteria produced in the lymph must be carried in the lymph and be inoculated with it in the human subject. Experimenters recognizing the strong position taken by the anti-vaccinationists in reference to these facts, have been trying for years to produce a lymph devoid of bacteria, or failing in this, to effect the destruction of the pathogenic bacteria before using it for vaccination purposes. The former condition being impossible, efforts have mainly been directed to the destruction of these organisms without injury to the lymph.

Carsten and Coert, in 1875, found that sufficient heat to kill the bacteria also destroyed the lymph. Attempts at filtration were then tried, resulting as I previously mentioned, in the destruction of the lymph. Copeman, in 1891, published the results of some investigations looking to the use of glycerin as a germicide, since Mueller, Straus and Chambon and Ménard had been using it for some time as a lymph preservative. He made a still further report in 1893. Here he states: "Lymph which originally gave only mediocre results, after fifteen days in glycerin produced a passible pustule; after forty, fifty or sixty days a typical one. The improvement seemed due to the gradual extinction of parasitic microbes under the influence of glycerin and time." After reading this report in 1894, I began the preparation of the glycerinated lymph, and, while my results were not so flattering as those of Copeman with glycerin as a preservative, there can be no doubt that it brings about gradually the destruction of the germs. The hay bacillus and the unidentified bacillus formerly mentioned by me being the only ones to survive any considerable time; and I am moreover of the opinion that the germs originally pathogenic are attenuated by the action of the glycerin, even though they may grow when planted on artificial media. This point, however, requires further investigation.

In October, 1894, Dr. Ralph Walsh of the National Vaccine Establishment, Washington, D. C., read a paper before the American Public Health Association, Montreal, in which after discussing Copeman's results, he says: "The admixture of glycerin with vaccine lymph will destroy all extraneous bacteria without injury to its peculiar active principle," and further, "the admixture of glycerin with vaccine lymph not only destroys extraneous bacteria but prolongs the activity of the lymph." In May, 1896, Dr. Sternberg, Surgeon-General United States Army, read a paper at Atlanta, Ga., in which the following conclusions were arrived at:

"Various bacteria are commonly found in the lymph from vaccine vesicles obtained either from bovine animals or from man. Among these are the well-known pus cocci and these micrococci are probably largely responsible for the erysipelatous inflammation and other unpleasant complications which frequently result from vaccination with such lymph."

Again, "lymph preserved in glycerin after a time becomes sterile so far as the presence of bacteria are concerned without losing its specific virulence."

In October, 1896, Dr. George H. Weaver of Rush Medical College read an article describing the bacteriologic contamination of vaccine lymph and the preservative action of glycerin. His conclusions are as follow:

"1. Vaccine lymph always contains bacteria, often of pathogenic forms.

"2. Pure vaccine lymph, after keeping in a fluid state or dried on ivory points as now prepared, is unfit for use and often dangerous.

"3. Vaccine lymph diluted with pure glycerin and distilled water becomes sterile in about two weeks and should not be used sooner."

In 1897 a committee consisting of Richard Thorne Thorne and Copeman, appointed by the Local Government Board of London to visit the cities of Europe and examine methods of preparing, storing and using vaccine lymph, reported in an exhaustive paper of over thirty pages the methods in Paris, Dresden, Berlin, Geneva, Brussels and Cologne. I can only give several extracts as follows:

"In only one of the places visited, namely, Paris, did we find that vaccination was carried out under official sanction with crude calf lymph, and even there the process was limited to vaccination direct from calf to arm; all lymph stored for distribution being glycerinated calf lymph."

Again, "The use of glycerinated calf lymph has become general throughout the German Empire."

Again, "Lymph obtained from these various sources and used from seven to thirty days after collection gives an insertion success of from 92 to 100 per cent."

These gentlemen are emphatic in their endorsement of this form of vaccine and recommend its adoption by the English Government, since in England at the present time arm-to-arm vaccinations are still largely in vogue. They also suggest, "That the Board's Animal Vaccine Station should be reorganized, both as regards construction and administration. *Notably*, will it be requisite that it should include a properly equipped laboratory under the direct supervision of a bacteriologic expert."

Now, assuming that the foregoing conclusions are correct, and that they are correct can not be successfully contradicted, we are allowed no other alternative than to condemn the use of vaccine crusts, quills, points, etc., or any other form of virus which has not been subjected to the purifying effects of glycerin or some similar agent. And now, a few words as to the methods of vaccination: On the Continent, a number of insertions are recommended, a small amount of the fluid is dropped on the skin in from three to five places and a sharp pointed lancet thrust once through the epidermis at each point desired to be inoculated. This puncture should be in an oblique direction and should extend only through the skin. In Paris, the lancet is charged with the lymph before the insertion. The theory for the number of insertions seems to be, that the vaccination more nearly approaches the point of saturation from multiple vesicles than from a single vesicle. This method is also recommended in this country by Dr. Hardaway of St. Louis, who suggests not less than five insertions one-half inch apart. Dr. Hewett of Minnesota modifies this by using a clean needle and making five pricks just deep enough to

start the blood and about one inch apart. "Then with the same needle charged with the virus, gently prick it into each wound carefully." His opinion is that at least four perfect vesicles are necessary to protection.

The general method in this country is to use the single scarification about the insertion of the deltoid and carefully rub in the virus. I am inclined to prefer the insertion method when using glycerinated lymph, since it is difficult to get the lymph to "dry," and many practitioners object to the time necessary for scarification to become "sealed up;" and there can be no doubt that careless manipulation is more liable to result in contamination in this than the insertion method.

It should be scarcely necessary for me to mention the necessity for cleanliness in the operation of vaccination, yet I am sure that many physicians are negligent in this respect, and it is more than probable that many of the bad results blamed on the lymph are due to faulty technic or slovenly methods of inoculation. It is probably this fact that suggested subcutaneous inoculation to Dr. Sternberg when he writes as follows:

"Immunity may be induced by the subcutaneous inoculation of vaccine virus without the development of a vaccine vesicle; and it is probable that the subcutaneous injection of lymph preserved in glycerin would give protection without any of the septic complications so common as a result of vaccination by the usual method."

The same fact was also noticed by Dr. Kinyoun in an article published in 1896, in which he says: "Subcutaneous inoculations are followed by slight inflammatory reaction, being less when the virus is well diluted. There is a slight engorgement of the vessels and occasionally a slight exudation at the point of inoculation, which disappears in a short time. There is no lesion accompanying subcutaneous inoculation." This question suggests room for future experimentation in the hope that it may eliminate so many distressing complications of vaccination which annoy the patient and are a source of anxiety to the physician.

PHYSICIAN TO COOPER HOSPITAL.
CAMDEN, N. J.

To comprehend the causes which led to the enactment of the present medical law of New Jersey, and the establishment of the State Board of Medical Examiners, it is necessary to review briefly the history of medical legislation in New Jersey and its effects upon the profession of the State.

The Medical Society of New Jersey was organized in 1766, on a voluntary basis, without incorporation or charter. In 1772, the Society secured from the Colonial Assembly the passage of

"An Act to Regulate the Practice of Physic and Surgery within the Colony of New Jersey," which provided . . . "that no person whatsoever shall practice as a Physician or Surgeon, within the Colony of New Jersey, before he shall have first been examined in Physic or Surgery, approved of, and admitted by any two of the Judges of the Supreme Court, for the time being, taking to their Assistance for such Examination such proper Person or Persons, as they in their Discretion shall think fit, for which service the said Judges of the Supreme Court as aforesaid, shall be Entitled to a Fee of twenty shillings, to be paid by the Person applying. . . ."

The law also provided that a "Testimonial of Examination and Admission" to practice should be given to each success-

ful candidate; . . . that the penalty for violating the law should be "five Pounds"; . . . that the act should not apply "to any Person bearing His Majesty's Commission and employed in his Service as a Physician or Surgeon," or . . . "to hinder any Person or Persons from bleeding or drawing teeth," or . . . "to skilful Physicians or Surgeons from neighboring Colonies," but . . . "that every Physician or Surgeon or Mountebank Doctor who shall come into, or travel through this Colony, and erect any Stage or Stages for the sale of Drugs or Medicines of any Kind, shall for every such Offense forfeit and pay the sum of Twenty pounds, Proclamation money."

In 1784, this law was re-enacted by the State of New Jersey; its examining provisions were retained, and it remained in force until 1816. In that year, the Medical Society of New Jersey was re-incorporated (the first incorporation having been made in 1790); the act of re-incorporation authorized the Society to appoint a Board of Censors from its membership, to examine and license all applicants to practice medicine and surgery in this State, and this authority was possessed exclusively by the Society until 1851. In that year, the system of censorship was bitterly complained of by medical colleges in New York and Philadelphia as inimical to public and professional interests; the cry of monopoly was raised: the law was attacked and subsequently amended to permit the graduates of the College of Physicians and Surgeons of New York, the University of the City of New York, the University of Pennsylvania, the Jefferson Medical College and the Medical Department of Pennsylvania College, to obtain licenses from the Medical Society of New Jersey, without examination, upon the presentation of their diplomas to the President of the Society. In 1854, the friends of indiscriminate license secured the passage of an Act admitting the graduates of any legally incorporated medical college to practice medicine and surgery in New Jersey, upon filing a copy of their diplomas with the clerk of the county in which they intended to practice. This law practically abrogated the examining and licensing power of the State Medical Society and, in 1866, the Society voluntarily surrendered to the State the empty privilege of censorship.

From 1772 to 1851, a period of seventy-nine years, the Medical Society of New Jersey stood as the authorized guardian of the portals of the medical profession of the State; from 1854 to 1880, a period of thirty-six years, the only legal requirement for license to practice was the registration of a medical diploma. During the latter period, physicians multiplied rapidly; the doctor was despoiled of much of his former dignity; bogus medical colleges flourished, and quacks abounded in every part of this State. The need of restrictive measures, governing the practice of medicine, became evident and, in 1880, an Act was passed by the Legislature making the filing of a fraudulent medical diploma a misdemeanor. This law, however, was not sufficient to shut out the possessors of such diplomas from active practice, or to stop the work of bogus medical colleges. Both the profession and the laity recognized the necessity of a reconstruction of the medical law on the basis of State supervision over the requirements admitting applicants to practice medicine. To meet this need, the State Board of Medical Examiners was instituted in 1890, and during the first year of its organization more than three hundred irregular practitioners were driven from the State. The next step in medical progress was the enactment of a law in 1892, regulating the practice of midwifery, which provided for the examining and licensing of

midwives by the State Board of Medical Examiners, and their registration in the office of the clerk of the county in which they practice. In 1894, the medical practice act was revised, under the provisions of which the present State Board of Medical Examiners is now operating.

The present medical law of New Jersey provides for a State Board of Medical Examiners, consisting of nine members appointed by the Governor and confirmed by the Senate, and containing five regular physicians, three homeopathic, and one eclectic physician. Examinations are held in the following branches of medicine and surgery: "(Sec. 1) materia medica and therapeutics, (Sec. 2) obstetrics and gynecology, (Sec. 3) practice of medicine, including diseases of the skin, nose and throat, (Sec. 4) surgery, including diseases of the eye, ear and genito-urinary organs, (Sec. 5) anatomy, (Sec. 6) physiology, (Sec. 7) chemistry, (Sec. 8) histology, pathology and bacteriology, (Sec. 9) hygiene and medical jurisprudence," exclusive of the materia medica and therapeutics of homeopathy and eclecticism, in which the graduates of those systems are examined by their respective representatives on the Board. The composition of the Board has proved harmonious and the methods of examination equitable, during the eight years of the Board's existence.

The academic requirements of the medical law are those of a common school education, which the State Superintendent of Public Instruction has defined to consist of, "Orthography, arithmetic, English grammar and composition, geography, history of the United States, algebra and physics, or what this Board may consider their equivalent."

In no instance is an applicant permitted to come before the Board for examination unless the requirements above named have been fully met.

The medical requirements of the law call for, "A diploma conferring the degree of doctor of medicine from some legally incorporated medical college (which in the opinion of said board was in good standing at time of issuing said diploma) in the United States, or a diploma or license conferring the full right to practice all the branches of medicine and surgery in some foreign country, and have also studied medicine four years, including three courses of lectures in different years in some legally-incorporated American or foreign medical college or colleges prior to the granting of said diploma or foreign license; provided, however, that two courses of medical lectures, both of which shall be either begun or completed within the same calendar year, shall not be considered to satisfy the above requirements."

These requirements are also strictly insisted upon in the case of every applicant for examination.

A total average of 75 per cent., or 675 points is necessary "to license a candidate (he or she having otherwise complied with the law) providing that in no one section shall the percentage be less than 50, in which case, however, the candidate may be granted a second examination immediately upon that Section. A candidate having less than 50 points in more than one Section shall be rejected, regardless of the total average."

The examination papers, together with applications for examination are deposited in the State Library at Trenton, after examinations.

At the present time, this Board endorses the certificates of examination and license issued by the Med-

ical Council of Pennsylvania and the Board of Regents of New York, together with the applications of those physicians who are now, or have been members of State Examining and Licensing Boards of other States. It is the desire of this Board to extend the privilege of endorsement to the licentiates of any State Board whose academic and medical requirements are substantially the same as those of this Board. Reciprocity of State medical license is due to the profession. The subjecting of medical practitioners of long standing to a technical examination is unnecessary and unjust. Reciprocity, however, can not be successfully carried out until a uniform minimum standard of academic and medical requirements is adopted by the different State Examining Boards.

This Board has the power to refuse to grant, or to revoke, a medical license for cause. The revoking power has not, as yet, been exercised except in the case of midwives. Neither is it likely to be exercised unless physicians have been previously convicted of criminal abortion or crimes involving moral turpitude.

The law regards as practitioners of medicine those persons who use a medical title, with or without license, or without the use of such title, engage in the customary duties of a medical practitioner, and it is framed to include the practice of mind-healing, faith-cure and similar systems.

Violation of a medical law constitutes a misdemeanor, punishable by fine or imprisonment, or both, and it is mandatory upon the district attorney to prosecute such cases when duly brought to his attention.

The act does not apply to surgeons of the United State Army, Navy, or Marine-Hospital Corps, while so commissioned; to internes of charitable or municipal hospitals, or registered dentists, or to legally qualified physicians of other States called in consultation, provided that such physicians do not open offices or places for the practice of their profession.

The medical law of New Jersey is an admitted necessity and has become popular with the profession throughout the State. It has elevated the standards of the profession by its academic and medical requirements, by its unceasing opposition to illegal practitioners, and by its supervision over practitioners of midwifery. It meets the demand of the people that the license of the State should guarantee that its possessor is qualified to conserve the public health. By its early demand that its medical diploma should only be given after four years of medical study, it has contributed to the extension of the curriculum of medical colleges, and to the organization of other State boards. It has proved itself a factor of incalculable benefit to both the profession and the public.

GONORRHEA IN THE MALE.

BY J. O. MALSURRY, M.D.

PERU, IND.

Gonorrhea is an acute, specific, infectious, systemic disease, with a local manifestation and systemic reaction. I am well aware that this statement is in variance with the almost universal statement of authors, but not so completely so with the clinician and more especially with the patient or victim. The victim of this disease, if allowed to tell his story, will give a history in the mild cases, which are but slightly infectious, of an aching in the limbs and back, just at the time of agglutination of the meatus, which, by the

way, is a sign that precedes by some twenty-four hours the tingling or itching in the end of the penis, or the pearly drop, so often spoken of. This acute symptom or aching will subside, usually, with the appearance of the discharge, when the local symptom (discharge) becomes the marked one, in fact the only manifest symptom. This is a point to be noted, since in the severe infectious cases, if the discharge be free at the time of severe or pronounced systemic reaction, it will all but cease during such severity, to be re-established when the severe symptoms have subsided.

This symptom (discharge) has been bombarded from time immemorial, with all sorts of topical applications and injections, and more recently with the bichlorid douche, all of which have had their so-called or supposed cures. It is universally admitted that in no other local inflammatory condition have efforts proven so uniformly unsuccessful. Some would explain this fact with the reasoning that the micro-organisms have already developed, penetrated the epithelial layers and formed colonies in the lymph spaces and connective tissue layers of the mucous membrane so effectually, before local treatment is begun, that no remedy will reach the deeper-seated organisms short of entire destruction of the mucous membrane.

The fact of the matter is that the symptom (discharge) is being treated under the guise of removing the cause, *i. e.*, destroying the micro-organisms, which is the sole and local cause of the discharge or disease. Suppose this to be the case; an ounce of pus would be a conservative estimate of the quantity of discharge thrown off in twenty-four hours; this, according to the local idea, must be formed within and of the penis by the micro-organisms. Now, if such were the case, the average victim would run out of penis long before the admitted time (some twelve to twenty days) for the discharge to even lessen in quantity. This discharge is a product of the body, either local or general, and certainly not local in the sense of tissue or cell destruction, for the reasons pointed out above. It must, therefore, be a product of the body in general, and gathered up and thrown off through the agency of the blood vessels or lymphatics, or be a product, *per se*, of the blood or lymph, or both, and is kicked out by nature through this particular door (urethra) through which the disturber entered, be that the gonococcus of Neisser or what not. The adherents of the local theory of this disease would account for the pus in that it is an ordinary product of a local suppurative inflammation, which is made up of leucocytes which escape from the local blood vessels in consequence of changes wrought in their coats by the local inflammatory process, including debris from broken-down epithelium, etc. This is a very fine theory, and would be more acceptable had these same adherents furnished an infallible local remedy, or shown that the phenomena following a poisonous snake bite to be a local inflammation.

In the more severe cases we have, in addition to the above symptoms, at about the end of the third week, more pronounced systemic symptoms; oftentimes a chill followed by fever and elevated pulse which, by the way, runs a little high throughout the entire acute attack, even though the temperature be all but normal; which fact shows an element of sepsis. There is a loss of appetite, coated tongue, foul breath and a feeling of lassitude together with the local symptoms,

in the posterior urethra, of pain and tenesmus, supplemented by frequent urination and oftentimes great distress during voidance of urine. The excretion of pus here will not be so abundant and that from the posterior urethra, back of the cut off muscle or external sphincter, will be thrown into the bladder and passed off with the urine. Here we have systemic symptoms almost as pronounced as in diphtheria or scarlet fever, with local treatment as ineffectual as in the above diseases. And yet, we are taught that we are dealing with a local disease, as the old writers taught diphtheria to be; but which is now universally recognized to be a systemic affection, with all but, if not quite, a specific (antoxin) for its cure.

We have yet another type of gonorrheal infection, which might very properly be termed gonorrheal septicemia. This condition is peculiar to the third or fourth week of the infection and but rarely, if ever, occurs at the acute onset of the disease. This sepsis is announced, as most septic troubles, by a pronounced chill followed by fever; 103 to 105 degrees F., and in fatal cases 108 degrees F. has been recorded. This temperature is of an intermittent character, dropping to about normal and rising to the high point once in twenty-four hours. This peculiar temperature points to a multiplication of the specific element up to the point of an explosion, or ovulation, if you please, the temperature rising and falling with the above phenomena.

Now, whether all of these conditions and shades of the same disease are due to one and the same cause or specific element, no one is able to answer positively. Some attribute it to a mixed infection, while others think it due to a susceptible system. As for myself, I am sure that we are called upon to meet these different shades of the same disease, the same as we are in diphtheria, scarlet fever, typhoid fever, etc., let the cause be what it may. It is very generally admitted that paralysis is sometimes a sequel of diphtheria, and nephritis of scarlet fever. This, to be sure, is in consequence of the systemic character of the diseases. A species of rheumatism is admitted to be a sequel of gonorrhea. Then is it not reasonable to suppose, from this fact alone, that gonorrhea is a systemic disease in the same sense as diphtheria and scarlet fever? When we point out the distinction between infection and inflammation, we have an explanation of the chronic cases of gonorrhea. Infection is a condition in which foreign media of irritation have gained access to the body either mechanically or by means of their products disturb its functions. These media are capable of being transmitted to other individuals; in most, if not in all cases, the invading irritant is of bacterial origin. The organisms, unless arrested, are prone to multiply, to spread into new territory and to transmit their toxic products to the general circulation. This, in my opinion, is exactly what occurs in gonorrhea infection. The clinical evidence is all conclusive of this fact; and if we were in need of further proof, we have only to look into the therapy applied to this disease for the past centuries and up to the present time. The local territory invaded or irritated by the organisms and their toxins becomes a center to which leucocytes in large numbers rapidly migrate, and in this way the process known as seroplastic infiltration is established. By this infiltration, a limiting wall is formed around the infected space. The formation of the limiting wall gives rise to heat, redness, pain and swelling; the phenomena of inflammation. In this

view of the facts, inflammation is not really the disease, but effort to limit the disease. This wall confines the infective process to narrow limits and may protect the general system against the further infection after the initial poison has run its course; that is to say, nature has generated an antitoxin which overcomes the offending element (toxin) and the disease, so far as the general system is concerned, is at an end. We have now to consider the functional conditions of the different organs, as the liver, spleen, etc., especially where there has been severe systemic infection, while the pathologic changes will apply more especially to the urethral canal and appendages.

This brings us to so-called chronic gonorrhea or gleet, and the above explains the phenomena of the same, which is in reality only the resultant damage done the local tissue furnishing a lurking place for the remaining micro-organisms, but at the same time they are fenced off from the general system by the plastic exudate as a result of the inflammation, as has been described, but are ever ready for a new field.

Treatment in the acute stage of this disease must be largely expectant, since we have no specific to be given internally or applied locally, which will cure the disease. Our efforts then, in the present light of the etiology and treatment of this disease, will be confined largely to prophylaxis, keeping the phenomena of the disease in the middle of the road, so to speak, and preventing complications until the race is finished, or at least slowed up sufficiently to begin the repair of damages.

To strike a direct blow at the phenomena of this disease with the idea of destroying it *per se*, has proven to be a failure with the past and present therapy, as is proven by clinical facts, notwithstanding the comparatively recent developments in the etiology of this disease and therapy applied with special reference to this etiology. Even though good results have been reported, the tide is beginning to ebb and we have only to wait for another swell.

During, then, the acute stage, which will usually be from twelve to twenty days, we can not do better than to keep the parts thoroughly cleansed, the patient quiet as possible, a glass of Hunyadi water each morning, and a hot hip bath including the genitals twice or thrice daily, remaining in the water from twenty to thirty minutes. This is to be continued until the discharge becomes lessened and at the same time thinner; at which time balsam copaiba and oil of cubebs should be given as freely as the stomach will admit of, and at the same time an astringent injection should be used, preferably perhaps of an antiseptic character, as nitrate of silver, bichlorid of mercury, etc. I prefer, however, for this subacute stage, an injection of acetate of zinc, from two to sixteen grains to the ounce of water, or one dram of subnitrate of bismuth to one ounce of equal parts of water and glycerin. The injection to be repeated, at first following each urination and finally to be used each evening for a week or ten days after the complete disappearance of the discharge. This treatment applies to cases where the local symptoms are confined to the anterior urethra. The involvement of the posterior urethra is suggestive of a new infection of the general system, since it invariably occurs at about the end of the third week, the universally recognized time for the acute infection to begin to subside; and too, the symptoms (systemic) are the same as at the acute infection, only more marked. I am led to believe that these marked

symptoms and severity of attack are due, at least in a measure, for the want of a free exit for the pus, and in consequence more of its elements are retained in the blood to be thrown off through other channels. The same phenomena, in a slighter degree, occur when a strong astringent injection is used in the acute stage of the disease, which inhibits the discharge. It is a notable fact, also, that the period of decline here corresponds very closely to that of the initial infection; showing a probable repetition.

This extension or new infection, as the case may be, is important not only on account of the painful symptoms to which it will usually give rise, but also on account of the fact that, by greatly increasing the extent of the local inflammation, it renders complete recovery much more uncertain and remote, and by its proximity to other important organs greatly enhances the probability of a further extension of the inflammation to the bladder, seminal vesicles and testicles. And too, the more local surface involved increases the local inflammation and in consequence the plastic exudate, which is slow to be absorbed, and hence the great danger of permanent pathologic conditions. In severe cases of this character, absolute rest in bed must be enforced. As a diuretic for such cases, secure the daily consumption of from two to five quarts of plain water, and to this may be added boric acid or salol in doses of five to ten grains of each, four or five times daily. For the pain and tenesmus, rectal suppositories of morphia and belladonna will be found efficient. After the acute symptoms have subsided, copaiba and cubebs will be indicated until all acute inflammation has completely disappeared; then, if there yet remain any pus formation in this region, which will be ascertained by an examination of the urine, a deep injection of a solution of nitrate of silver, 1 to 8000, will be indicated.

A catheter is to be introduced just through the external sphincter and two or three ounces of the solution thrown in slowly, with any suitable syringe, which will pass into the bladder after medicating the posterior urethra. The solution is to be retained for a few minutes, then passed out through the urethra, which will medicate the entire urethral tract. For chronic cases of the posterior urethra, the same procedure may be carried out, gradually increasing the strength of the solution. In stubborn cases of this character, of which there are many, the use of sounds will lend assistance in breaking up adhesions and causing absorption of the plastic exudate.

Where the posterior urethra alone is involved, which is usually the case in these especially stubborn cases, suppositories introduced, of an astringent or even caustic character, will often give good results. Instillation of a few drops of a solution of nitrate of silver of from one to five grains to the ounce of water, just following the complete stretching of the posterior urethra with the sounds, will often prove effectual. I am ready to admit that in these chronic cases as well as the subacute, local medication alone is effective. Not because the remedies used destroy the specific element *per se*, but from their local effect in stimulating the tissue to a healthy action and thus bringing about the normal vitality, which, after all, is probably the prime factor in eradicating disease. Since it is always an astringent that yields good results in these cases, it would be natural to surmise that owing to the relaxed and softened condition of the coats of the local blood vessels, there is an escape

of serum, which, through its dissolving or softening effect will not allow the epithelium to reproduce. The astringent supplies this deficiency, puts on a splint so to speak, checks this exudation and at the same time assists in restoring the coats of the vessels. In this way, then, the epithelium is reproduced, which shuts off the lurking place of the specific element, which must then move on, rather than be destroyed by the topical applications. For this reason I am not an advocate of strong, or weak for that matter, antiseptic remedies, further than their astringency. For the same reason we are not confined to any one remedy, but the principles of astringency, which may be obtained from many and various remedies, which fact probably accounts for the great number of remedies employed in the treatment of this disease, by as many different clinicians, all apparently with good results when applied in the proper manner, and more especially, at the *proper time*, which, as I believe, is never during the acute stage of the disease, for the reasons pointed out above. The action of the copaiba and cubebs is astringency and is of no avail during the immediate acute stage, but on the other hand will increase constitutional symptoms when used at this acute stage for the same reason pointed out as to the astringent injection at this period, that of inhibiting the discharge and causing the elements of the same to tarry longer in the system and finally be cast off through other channels.

The great value in these two remedies lies in their mode of application, *through the urine*, thereby avoiding all instrumental irritation, which is no small factor, especially where the posterior urethra is involved. If the case is chronic and of long standing, which is equivalent to extensive exudate, these remedies must be displaced by astringents which will penetrate deeper, and just here is where we get the good effect from the use of the sound preceding the injection or instillation; the tissue is rendered more susceptible to the remedy, hence a weaker solution may be used with better effect than a stronger one and with less pain, which is no small item to the patient, and many times financially to the physician.

It matters not in what portion of the urethral canal the disease may be located, all mechanical obstacles must first be removed or no form of medication will be successful. If located in the membranous or prostatic portion, gradual dilatation with sounds will give the best results. When there are strictures of the pendulous portion, division is perhaps the best method of removing them.

In gonorrheal septicemia treatment which applies to sepsis in general seems to offer the best results, such as limiting the absorption of the toxins, if such can be the case. It is probable, however, that in gonorrheal septicemia there is but one time of absorption and that is at the onset, after which there is a septic element in the blood which multiplies and explodes, as has been described. The object here, then, will be to use a remedy or remedies which will destroy the septic element or its power to multiply, and to bolster up the blood so as to give it the best possible resistance to the invading septic element. For the first part, quinin at a single dose of 20 to 30 grains is given some five or eight hours preceding the chill; this is to be repeated as often as the chill repeats. For the second part, tincture of the chlorid of iron, solution of chlorid of arsenic, and bichlorid

of mercury seem to meet the requirements better than any other combination.

A word as to the irrigation method, with bichlorid solution or any other supposed abortifacient, of aborting or treating gonorrhea. I have given the bichlorid method careful trial in six consecutive cases and in each and every case there developed about the end of the third week posterior symptoms, and I have good reason to believe that this posterior extension or new infection, if you please, was due, at least in part, to the irrigating solution; since of six other cases treated about the same time, after the method pointed out above, there was only one case in which extension to the posterior urethra took place, and this was probably due to inordinate exercise—that of cycling. This irrigation brings about congestion and in consequence weakened epithelium, which is probably further softened by the too free use of water and rendered less resistant; and at the same time the infectious element is carried back from the anterior urethra and extension or new infection, as the case may be, takes place, which otherwise would probably not have occurred.

One case in particular had been a victim of this disease three times preceding this last attack, each preceding time the local symptoms confined to the anterior urethra, and each time making a complete recovery in from four to six weeks, with the plan of treatment above described in such cases. In view of his last experience, it is safe to say that there is one person who will never again submit to this irrigation method of treatment. The discharge was not so abundant in these cases; in fact, at times it would all but disappear, but at the same time the constitutional symptoms became more marked, the patient feeling and looking badly, with an elevated pulse and temperature.

ASSOCIATION NEWS.

American Medical Association.

Official Minutes of the General Sessions of the Forty-ninth Annual Meeting, held in Denver, Colo., June 7, 8, 9 and 10, 1898.

(Concluded from page 95.)

JUNE 10—FOURTH GENERAL SESSION.

The Association was called to order at 11 A.M. by the Fourth Vice-President, Dr. Happel.

The Secretary read the minutes of the previous general Session, at the conclusion of which Dr. I. N. Love of St. Louis, said: The minutes that have been read apply to a very important part of our work, and very little is said about the report of the Business Committee of yesterday. In the report of the Business Committee of yesterday there were fourteen different matters, if I remember rightly, that were considered, and most of them were quite important. We know that when these minutes are accepted and printed they are the action of the Association, and it seems to me, Mr. Chairman, there were several items concerning which the minutes are not clear. They are not distinct, not definite. I have forgotten the exact wording of the resolution offered by Dr. Bailey, which pertained to the appointment of a General Secretary, but the motion I offered in regard to it was that, inasmuch as the resolution involved the appropriation of money, it be referred to the Board of Trustees, which is the disbursing organization of the Association.

Secretary Atkinson—I have no motion in writing pertaining to that report.

Dr. Love—I move, Mr. President, that the minutes be corrected so as to read, "Resolved, That inasmuch as the resolution of Dr. Bailey pertained to the disbursement of money, that it be referred to the Board of Trustees for consideration, and report back to this Association one year hence."

I am surprised that the Secretary did not take down the

substance of the motion made by me at a preceding General Session. Seconded by Dr. Ferguson.

Dr. H. D. Didama—I would like to ask whether there was any record made of such a motion by the stenographer. We suppose that the auricular appendages of the stenographer are sufficiently acute to catch all of these things, and I would like to know if the stenographer has any record of it.

(Secretary Atkinson accidentally missed a line or two relative to the action taken on Dr. Bailey's resolution in reading the minutes, and while the stenographer was searching his shorthand notes, Dr. Atkinson discovered his omission, and then read the substance of Dr. Love's motion.)

The President—It is my recollection that the motion made by Dr. Love was that, inasmuch as the resolution involved the appropriation of money, it was referred to the Board of Trustees. The Chair can not state, however, whether it was in the form of a well defined motion or not. This matter brings us to the point that if the stenographer represents the JOURNAL or the Association in his work, and is paid by the JOURNAL, he should furnish every morning a typewritten copy of the minutes, *verbatim et literatim*, to the Association. The members have a perfect right to correct the minutes. If the minutes are thought by the majority of members present to be incorrect, not as full as they ought to be—if they are not a true exponent of the will of the Association, they should be corrected.

After Dr. Atkinson had read his minutes pertaining to the motion of Dr. Love, Dr. Love said: I wish to say a few words, Mr. Chairman, from the business standpoint of this Association. Important resolutions and important actions taken by this body have for years not appeared in the official minutes. We have had from year to year just such evidences of secretarial inefficiency—absolutely—and I say now, without fear of contradiction, that the action on the resolution or motion offered by me was not read by Dr. Atkinson. He overlooked it. No man should attempt to read the minutes of an important Association like this from illy prepared notes. And, Mr. Chairman, in all kindness I will say, that I am surprised at the fact that in the reading of the report of the Business Committee and the action taken upon the particular section under consideration, we have very imperfect records. Dr. Atkinson has read from his notes that which he did not read in the beginning.

Dr. Atkinson—I was under the impression that I read the paragraph mentioned by Dr. Love, but it seems I did not do so. I wish to say in this connection that if the Secretary of the Business Committee had not carried off the resolutions that were introduced at the previous session, these mistakes would not have occurred.

Dr. H. D. Didama of Syracuse—I would like to inquire if it is the practice of the Business Committee, after reading their report, to carry it off? It seems to me it should have been handed to the Secretary. Our Secretary, Dr. Atkinson, has been placed at a great disadvantage in the matter of his minutes, owing to the fact that the Secretary of the Business Committee has carried off the reports which should be in his possession.

Dr. I. N. Love—In all kindness I desire to say, that I gave up the Loop trip simply for the reason that I felt that this was the most important meeting of the Association, inasmuch as action has to be taken upon the minutes as to the report of the Business Committee of yesterday. Time and again important reports have been made during the closing moments of the Association and hastily imperfect minutes of important records have been presented and allowed to go by carelessly and indefinitely. To show you, gentlemen, that I am not springing any new thought, I will say that at the Baltimore meeting, and at numerous other meetings, there have been severe criticisms passed upon the Secretary. Dr. William Osler made a statement at Baltimore, as representing the local Committee of Arrangements there, which severely reflected upon the Secretary of this Association. Unfortunately, he made the criticism in a very severe manner. But I understand that important resolutions presented at previous meetings of the Association have been left out of the printed records. One important resolution, an amendment to the Constitution, which affected the position of the Permanent Secretary, was left out of the minutes by the Secretary. I wish to say, in all kindness, that the office of Secretary is not a sentimental office. The office of Secretary is the business end of the Association, and I would advise the Secretary hereafter to see to it that the stenographer, paid by the Association, shall take a record of every point made regarding reports.

Dr. J. W. Graham, of Denver—Every one knows that it is a very difficult thing for a secretary who is not a shorthand writer to take notes of all business that is transacted in the general sessions of an Association like this. I do not think we

should expect our Secretary to do it. No man can do it. In this age we have specialists for this kind of work, and it seems to me that the stenographer should have his report prepared at all times, ready to be read. It seems to me that the stenographer can clear up these matters by reading his notes, and that we should look to him for a full report instead of to the Secretary.

(The stenographer told the Chair that he was ready at any time to read his shorthand notes when called upon to do so.)

Dr. Atkinson—There would be no trouble in keeping the minutes of the Association, if the members wrote out their resolutions and handed them to me. (Applause.) My friend, Dr. Love, refers to an omission at the Baltimore meeting, and I will say that it was caused by the neglect of the person who offered the amendment to present it to me in writing, and I notified the editor of the JOURNAL of this fact when I sent my minutes to him to be printed in the JOURNAL. I wish to say in defense of myself that I have always been in the habit of keeping in regular order every motion or resolution that was offered and handed to me in writing. When it comes to making a stenographic report of the amendments introduced on the floor, it is another thing, and I hope from this time forward the President will demand, before any action is taken upon any resolution or motion, that it shall be presented in writing to the Secretary. (Applause.)

Dr. Love—I make the point, Mr. Chairman, that the Secretary has been in the service of the Association for twenty-five years, and that it is his duty, at all times, to assist the Chair. I do not believe a single motion pertaining to any one of the Sections contained in the report of the Business Committee was called for in writing. I agree with the Secretary that every resolution pertaining to anything should be put in writing. It is the duty of the Secretary to offer suggestions to the Chair, because we are here for executive work. Those gentlemen who have lent their sympathies this morning with the Secretary have very little knowledge of the records of the past. I am not alone in making this statement. I am willing to be criticised, if necessary, but those who know me know that I would rather remove my right hand than to be unjust to any man. (Applause.)

(No action was taken on Dr. Love's motion.)

The President—The minutes are a little indefinite in regard to the action taken by the Business Committee on the suggestions contained in the President's address, and I will ask the stenographer to read his shorthand notes on that point.

The stenographer then read part of his notes of the report of the Business Committee on the President's address, as follows:

"While your Committee is duly in sympathy with the recommendation of the President as to the admission of members to the Association under the conditions mentioned, still under the existing laws of the Association it does not feel competent to recommend its adoption."

The President—The minutes are now clear on that point.

Dr. W. L. Wills of California, offered the following amendment to the Constitution:

Article IV—Officers. Amend to read: "The following officers, President, four Vice presidents, Treasurer, Librarian, Secretary, Assistant Secretary and Chairman of the Committee of Arrangements shall be nominated by a special committee of one member from each State represented at the meeting, and shall be elected annually by the vote of a joint ticket, and shall hold office until their successors are elected." (Lies over for one year.)

Dr. T. J. Happel of Trenton, Tenn., offered the following:

Resolved, That an exact time be fixed at future meetings of the Association by the Committee of Arrangements for the different General Addresses to be delivered before the American Medical Association, and that when that hour arrives all business must be laid aside until the Addresses have been finished.

Seconded by Dr. Love and carried.

Dr. C. Lester Hall of Kansas City, Mo., offered the following:

Resolved, That it shall be the duty of the Permanent Secretary to furnish the incoming Secretaries of Sections with a list of the names of those attending the various Sections each year. Seconded.

The Secretary—In moving the adoption of this motion I would like to make a remark. I would say, Mr. Chairman, that for a number of years I have sent a note to the Secretary of each Section asking him to keep a registration book for the purpose of containing the names of those who attended the Section, and this year I have had two Sections that have agreed to do this and have promised to turn over to me the registration book. I shall, in accordance with this resolution, if adopted, do as I have done before, write a note to the Secre-

tary of each Section asking that he keep a registration book.

Dr. Love, speaking to the resolution offered by Dr. Hall—I would suggest that every member of the Association when he registers place the name of the Section which he will attend and in which he will vote for Section officers. It seems to me if a record of the registration is kept by the Secretary of the General Sessions it would very easily enable him to furnish, as requested by the resolution, a complete list to the incoming Secretaries of all registered members in each Section. We all know that secretarial duties are burdensome; that they require experience and special adaptation. The Secretaries of the Sections are oftentimes selected hastily, with a view, possibly, to their prominence as practitioners and workers, knowing little about their secretarial positions. While it is difficult to secure efficient secretarial work from the different Sections, it seems to me it would be the easiest thing in the world for the Permanent Secretary to furnish the information asked for in the resolution that has been read. That is all he needs to do. The resolution as offered was adopted.

The following are the officers of the various Sections for the ensuing year:

State Medicine—Arthur R. Reynolds, Chicago, president; W. P. Munn, Denver, secretary.

Stomatology—George V. I. Brown, Milwaukee, president; Eugene S. Talbot, Chicago, secretary.

Cutaneous Medicine and Surgery—W. T. Corlett, Cleveland, president; J. M. Blaine, Denver, secretary.

Diseases of Children—Henry E. Tuley, Louisville, president; J. L. Booker, St. Louis, secretary.

Surgery and Anatomy—W. J. Mayo, Rochester, Minn., president; M. L. Harris, Chicago, secretary.

Physiology and Dietetics—J. Weir, Jr., Owensboro, Ky., president; Lee Kahn, Leadville, secretary.

Obstetrics and Diseases of Women—A. H. Cordier, Kansas City, president; W. D. Haggard, Jr., Nashville, secretary.

Practice of Medicine—Frank Billings, Chicago, president; Carroll A. Edson, Denver, secretary.

Ophthalmology—Casey A. Wood, Chicago, president; A. H. Williams, Boston, secretary.

Materia Medica, Pharmacy and Jurisprudence—T. H. Stucky, Louisville, president; Leon L. Solomon, Louisville, secretary.

Laryngology and Otology—P. R. Holmes, Cincinnati, president; Emanuel Mayer, New York, secretary.

Dr. X. C. Scott of Cleveland, Ohio, read the following report of the Judicial Council.

REPORT OF THE JUDICIAL COUNCIL.

Your Council reports on matters referred to it, as follows:

They have ordered their Secretary to send all documents pertaining to the standing of the Santa Clara County Medical Society and Santa Clara County Medical Association, of Santa Clara County, California, to the State Medical Society of the State of California for adjudication and to report their finding to this Association.

The Secretary of the Council has been instructed to forward to the State Medical Society of Colorado, the charges and protest preferred by H. Angus Sims against H. W. Kirby and H. V. Towaner of Cripple Creek, Colo., for investigation and adjudication.

In regard to the matter of appeal of W. F. Barclay of Pittsburgh, Pa., the Secretary of your Council has been instructed to inquire of the State Medical Society of Pennsylvania why they have made no answer to the communication which was sent by your Council to said State Medical Society of Pennsylvania immediately after the annual meeting of 1897.

Your Council requests and insists that all communications, documents or papers received by the Permanent Secretary, pertaining to business or matters before or to be before the Council, shall be forwarded by him, upon their receipt, to the Secretary of the Judicial Council, and that such communications, documents or papers shall not be delivered or forwarded to any other member of the Judicial Council.

H. D. DIDAMA, President.

X. C. SCOTT, Secretary.

On motion the report was adopted.

Dr. I. N. Love—The Board of Trustees have presented the following recommendation: That the following Committee on Transportation be appointed to correspond with railroads as to rates, and make the best possible arrangements for the Columbus meeting. The Committee recommends Dr. H. L. E. Johnson of Washington, D. C.; Dr. I. N. Love of St. Louis, Mo.; Dr. Charles A. L. Reed, of Cincinnati, Ohio; Dr. X. C. Scott of Cleveland, Ohio; Dr. Starling Loving of Columbus, Ohio; and Dr. E. D. Ferguson of Troy, N. Y.

On motion, the recommendation of the Board of Trustees was adopted.

Dr. Mayer extended an invitation to the Association to visit Cripple Creek, and to become the guests of the medical society of that district.

On motion of Dr. Love, the invitation was accepted with thanks and the keenest appreciation.

Dr. X. C. Scott offered the following resolution, which was adopted:

Resolved, That the Permanent Secretary be required to bring the minutes of the Association of previous years so that they may be referred to if necessary.

Dr. I. N. Love offered the following:

Resolved, That the Permanent Secretary be required to have the stenographic report of the proceedings transcribed and ready for consideration and correction, if need be, each day before being adopted.

Seconded and carried.

The following resolution was offered and carried:

Resolved, That the Secretary be instructed to furnish a copy of the Constitution and By-Laws and Code of Ethics to the proper authorities who have the preparation of the program, with instructions to print the same in the regular official program each year hereafter.

Dr. Henry O. Marcy of Boston, offered the following resolution: As we are near the close of the session I rise to a question of privilege. We have all enjoyed the hospitalities of Denver in an exceptional way. For twenty-three years I have been a constant attendant upon the meetings of the Association; we have profited by the hospitalities and by the assistance of the various local committees in each of the different cities where we have held our meetings. Wherever we have met one city has tried to rival another, until we have been led to think that there was no end to hospitality. I am quite sure I voice the universal expression of opinion of the Association when I say that I have not heard anything else save that of *éclat* concerning the manner in which the profession and citizens of Denver have so royally received and magnificently entertained us. We have each and all of us had a rare opportunity of witnessing and of personally enjoying and profiting by the hospitalities of the entire city. First of all, we have to thank the Chairman of the local Committee of Arrangements Dr. J. W. Graham, who has been such an efficient chieftain, and to him personally would I ask that this Association extend its thanks. Then the various associations and corporations of the city have each vied with the other in doing everything possible to contribute to our comfort, pleasure and convenience. We also wish to express our thanks to the railroads for reduced rates, the public press for reports of the proceedings of our sessions, and the various associations, including the ladies, who have done so much to contribute to our comfort and happiness. We wish to return thanks to the citizens of Denver for the hospitality which we have received at their hands, and for the extraordinarily agreeable way in which they have made our visit pleasant, and for the delightful reminiscences which will ever come back in memory of the hours we have spent here during the last week.

Dr. Henry P. Newman of Chicago—In rising to second the resolutions offered by Dr. Marcy, I feel that every member of the Association will heartily second what he has said. Having come in contact with the Committee of Arrangements in a business way, which many of you have not, I wish personally to testify to the efficient work of all of the different departments, and I feel that we owe the local Committee of Arrangements our heartfelt thanks, who have contributed so much to the success of the meeting held in this city.

Dr. I. N. Love of St. Louis, Mo.—As a member of the Board of Trustees, I know I voice the sentiments of the entire Board when I endorse and emphasize all that has been said so eloquently and sweetly by Dr. Marcy. At the same time I wish to particularly emphasize our appreciation of and for the gentle, graceful and efficient manner in which the Chairman of the Committee of Arrangements, Dr. Graham, has conducted the work. It is rare, indeed, that a man is possessed of such executive ability as he has displayed, the ability to select the right man and the right set of men to do the work as well as it has been done here. I appreciate from an editorial standpoint the fact that the Chairman of the local Committee of Arrangements has demonstrated that he is superb in the use of the scissors in being able to clip from the great mass of the profession the right men in the right way, and place them with his paste at the right place, and this particular man has never been absent from his post—never. (Applause.)

Dr. J. W. Graham of Denver—I ask you to include in your vote of thanks the entire profession of Denver, and I wish to say that I do not think there is a better body of men on earth to co-operate with in such work.

The resolutions of thanks were then unanimously adopted by a rising vote.

Dr. X. C. Scott of Cleveland, Ohio, offered the following:

Resolved, That we extend a vote of thanks to the various traffic associations and railroads which have granted the concessions asked for by this Association.

Seconded and unanimously carried.

Dr. I. N. Love—I wish to offer the following:

Resolved, That a special vote of thanks be given to the Union Pacific, Texas and Gulf, Denver and Rio Grande Railways, etc., for the most extraordinarily liberal courtesies they have extended to this Association.

Seconded and unanimously carried.

The President (Dr. T. J. Happel)—The Chair would state that the idea of presiding over the General Sessions of the Association before arriving here had not entered his head; that it has been done on the spur of the moment, and if there have been any errors in the rulings of the Chair they are errors of the head and not of the heart. Everything was done with an effort to promote and expedite the business of the AMERICAN MEDICAL ASSOCIATION. I think the members will bear me out in the statement that the business that was transacted in the Association yesterday was for the purpose, if possible, of settling a matter, and that whatever rulings the Chair made they were not made for the purpose of wounding the feelings of anyone connected with the matter. I tried to do equal justice to all parties connected with the transaction. (Applause.) The Chair desires to extend to the Association his thanks for the order which was observed during the administration of the affairs of the Association, and to state he has never been in any organization which has behaved in a more orderly, respectful and respectable manner. (Loud applause.)

Dr. Happel then presented Dr. Mathews in the following words: As Vice-President of the AMERICAN MEDICAL ASSOCIATION, and of the administration which is just passing out, I take great pleasure in presenting to you the incoming President for the year 1898-9, Dr. Joseph M. Mathews of the city of Louisville, Ky.

Dr. Mathews was very warmly received. He spoke as follows:

Mr. President and Gentlemen of the Convention—Words fail me in trying to attempt to thank this Association for the honor they have conferred upon me. For nearly twenty years I have been trying in a humble way to serve this body. I have sat at the feet of the great men of this profession, and in accepting this distinguished honor from this great body, when I reflect back upon the days when this Chair was occupied by that venerable man, Dr. N. S. Davis, and my illustrious predecessor, Dr. Sternberg, I must say that I feel great diffidence in attempting to fill this Chair. Yesterday, as I looked over this great body and reflected that during the twenty years that I have been identified with the Association hundreds that I knew then are now dead and gone, it made my heart sad. One of the most pleasant things connected with the membership of this great body is that we make friends, lasting friends, friends that will serve us always, and in the interim between our sessions our hearts go back to our meetings, because we feel the warmth of their influence and know that their hearts went out to us, and it is my hope that not a single member will drop out of our number between now and the next meeting. It is sad to think that each year some one of our many friends has been taken away, and so the Convention goes on forever. I believe the time is near at hand when it will be recognized that if a man in the medical profession of the United States is not a member of the AMERICAN MEDICAL ASSOCIATION he is not a reputable doctor. (Applause.) I believe that each year will add to our ranks many noble men, and I want to ask the indulgence of the Association always for the younger men, that they may be cared for; that they may be taken into the embrace of the Association; that they may be made to feel at home always. By so doing we make better men of them; we make better doctors of them, and let us see to it that the membership be added to from the younger ranks of the profession. (Applause.) Gentlemen, during this year and the coming year I shall try to do my duty. I hope some one will offer a resolution thanking the presiding officer (Dr. Happel) for the efficient manner in which he has conducted the deliberations of this body. We are deeply obligated to him. Please, gentlemen, accept my hearty and sincere thanks for the distinguished honor that you have conferred upon me. (Loud applause.)

Dr. I. N. Love—I move you, sir, that a special vote of thanks be given to Dr. T. J. Happel of Tennessee, for the superb and skillful manner in which he has conducted the deliberations of this Association, and for the thoughtful care with which he has looked at every detail of the business management of our sessions. The efficient manner in which he has presided ought to be an example to every one who follows in the Chair. (Applause.) We also wish to thank Dr. J. L. Thompson of Indi-

anapolis, for his grace and skill as a presiding officer, and especially to thank Dr. Jayne, the local Assistant Secretary.

Seconded and unanimously carried.

Dr. J. W. Graham of Denver—I want to add a little more emphasis to the vote of thanks extended to Dr. W. A. Jayne of this city, the Assistant Secretary. It is rare to find a man who has filled the office so capably and so acceptably as he has done. He has been my right arm throughout the year, and has made it possible to make the meeting a great success. (Applause.)

There being no further business to transact, on motion, the Association adjourned to meet in Columbus, Ohio, the first Tuesday in June, 1899.

SOCIETY PROCEEDINGS.

Chicago Medical Society.

The annual meeting of the Society was held in the new Society rooms of the Stewart Building, Wednesday evening, June 29, 1898, with the President, Dr. FERNAND HENROTIN, in the Chair.

The Secretary read the minutes of the previous meeting, which were approved.

The Chairman of the Membership Committee, Dr. J. H. Stowell, reported favorably upon the following applications, and they were elected: Drs. D. H. R. Patton, J. E. Woodbridge, W. E. T. Michelet, C. C. Hunt, F. E. Bigelow, S. A. Mathews, F. A. Goetz, J. F. H. Lugg, A. C. Broell, Josephine A. Jackson, Emil Amberg and Walter L. Vercoe.

The next thing in order was the report of the Secretary, which was read by Dr. ARTHUR R. EDWARDS.

The report stated that from 1888 to 1897 there had been 615 additions to the Society, and that during the past year there had been an increase in membership of 231. Of this number two failed to qualify; three were suspended for non-payment of dues; eleven died and ten resigned. The Society had now a membership of 902, including those elected at this meeting.

The average attendance for the thirty-nine meetings during the year was 110.

On motion of Dr. Harris the report was accepted.

The Treasurer's report was read by Dr. S. C. Plummer, showing a healthy condition of the Treasury.

On motion this report was received and referred to the Auditing Committee.

Dr. ARCHIBALD CHURCH made a verbal report as editor of the Society, stating that the character of the papers that had passed through his hands during the year as compared with those of previous years was very much superior. Not only had there been a large increase in the amount of work done by the Society, but the individual character and tone of the papers from a scientific standpoint had been distinctly elevated as compared with previous years. Nearly all of the papers had been published in the *Chicago Medical Recorder*, and many of them simultaneously in other medical journals.

On motion of Dr. Ridlon, the report of the editor was accepted.

Dr. J. H. STOWELL, Chairman of the Membership Committee, stated that during the past year the work of the Committee had devolved upon Dr. Newman and himself, owing to the long sickness and finally the death of Dr. Paoli. The Committee had endeavored during this time to do its work conscientiously and faithfully. It had corresponded in a great many cases in regard to applicants to find out their standing, and while the Committee did not expect they had kept every man out that ought to be kept out, still it had tried to do so.

Dr. E. J. DOERING reported, on behalf of the Publication Committee, that for the ensuing year the *Chicago Medical Recorder*, the official organ of the Society, would not be able to offer any prizes on account of the increased expense of publishing the proceedings of the Society, this expense during the past year amounting to about \$1000.

The Committee awarded Dr. M. HERZOG a prize of \$100 for his paper on "Superfetation in the Human Race." And also a prize of \$100 to Dr. ARTHUR D. BEVAN for his contribution on "Surgery of the Gall-Bladder."

Dr. GRAHAM, a member of the Library Committee, said the Committee had held several meetings and conferences with the authorities of the Newberry Library during the year. The medical department consisted of 30,303 bound volumes, 25,000 pamphlets, and there were continually on file 450 different medical periodicals. The library was now more complete than it had ever been, and the authorities promised to make further additions in the near future, especially in the nature of reference books. The library, however, lacked odd volumes or

numbers of important periodicals. The trustees of the library would pay more attention to increasing its usefulness if the members of the profession in the city and surrounding country took more interest in it. The Committee and library authorities believe that much good could be accomplished by members of the profession corresponding direct with the Newberry Library. Their communications would receive prompt attention, and abstracts of medical journal articles would be furnished physicians at a small remuneration. The Committee recommends that a notice or announcement of this be published in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

On motion, the report was accepted.

The Necrologist, Dr. HERMAN PETERSON, reported the deaths of ten members during the year. On motion the report was accepted and placed on file.

President HENROTIN then delivered his address, in which he spoke of the establishment of permanent quarters for the Society, believing that no mistake had been made by inaugurating this movement, and in order to do this it was necessary to secure funds. The manner of securing these funds was outlined. He directed attention to the renewed interest taken in the work of the Society, the improvement in its quality, and the proper dissemination of the material brought before it.

The Society proceeded to the election of officers, with the following result: President, Arthur Dean Bevan; first vice-president, J. C. Hoag; second vice-president, Henry B. Favill; secretary, Arthur R. Edwards; treasurer, S. C. Plummer; necrologist, Herman Peterson. Board of Trustees: Drs. James B. Herrick, Frank Billings, and F. Henrotin, for three years; Drs. N. S. Davis, Jr., S. C. Stanton and Wm. H. Wilder, for two years; and Drs. John Ridlon, Sanger Brown, and Harold N. Moyer, for one year. Judiciary Committee: L. L. McArthur for one year; Harold N. Moyer for two years; F. Henrotin for three years. Membership Committee: J. H. Stowell for three years; Henry P. Newman for two years, and James B. Herrick for one year. Publication Committee: E. J. Doering for three years; Henry T. Byford for two years and Frank Billings for one year. Auditing Committee: D. W. Graham for three years; N. S. Davis, Jr., for two years, and Hugh T. Patrick for one year.

The revised Constitution and By Laws, after more or less discussion of certain sections, were adopted.

Dr. SANGER BROWN gave notice that he would amend Article 7, after Section 3, at the next meeting, so as to read that "Any member in good standing may become a life member upon the payment \$100, and shall thereafter be exempt from the payment of annual dues." In addition to this and following it in another paragraph he desires the change made that "Any life member who has been a member of the Society for ten years may be elected to Fellowship upon submitting to the Society satisfactory evidence of fitness for such distinction."

Dr. D. W. GRAHAM also gave notice of an amendment to be offered by him at a subsequent meeting.

Secretary Edwards was voted an honorarium of \$250, and the Treasurer an honorarium of \$200.

The editor of the Society will not accept an honorarium of \$200 during the coming year, but asked that the money go towards furthering the interests of the Society.

Dr. SANGER BROWN spoke of the great importance of having the medical library located in the heart of the city, saying that if it was located down town many of the members could spend an hour or two hours a day with profit in consulting medical literature, and urged that a committee be appointed by the president to agitate this matter.

Dr. TRUMAN W. MILLER stated that the trustees had taken this matter up.

Dr. D. W. GRAHAM thought it was a mistake to abolish the Library Committee, saying that the committee had had the subject under consideration for a year, getting facts and information and had possible plans in view. The information the committee had received was that the Crerar Library would be glad to have a medical department. The other two factors to be considered were the moving of the medical department of the Newberry Library to the Crerar Library. In order to do this it would be necessary first to obtain the consent of Dr. Senn and second the consent of the trustees of the Newberry Library, and undoubtedly this could be obtained.

President HENROTIN thought the Board of Trustees as a body would have more influence in effecting such a change than a committee of three.

The President then appointed Drs. Doering and Miller to escort the newly elected president to the Chair.

Dr. BEVAN was very warmly received. He thanked the Society for the distinguished honor conferred upon him and said he would pledge himself to take a very active interest in the work during the coming year, and he would endeavor as

far as possible to carry out the very broad scheme that had been inaugurated by his distinguished predecessor.

The Society then adjourned until the second Wednesday in September.

Chicago Ophthalmological and Otological Society.

Discussion on Dr. Hotz's Case.

Dr. WÜRDEMANN—This morning I removed an eye I had been nursing for four weeks, not believing that it contained a foreign body. I first saw the case a day and a half after the accident, when I found an ulcerated wound of the cornea, prolapse of the iris and evident infection. The prolapse was cut off and the infection treated. The history of the case seemed to show that the foreign body was a large one, and I did not believe it to be in the eye. Three weeks after, a skiagraph was made which showed the foreign body to be present. This morning I tried to remove the foreign body after incising the cornea, but I was unable to do so with the magnet and had to remove the eye. The foreign body was found in the eye, covered with firm exudate. In six cases I have removed pieces of steel with the magnet from the iris and the lens, but have never removed a piece from the vitreous. I believe it possible to do so only immediately after the accident.

Dr. PINCKARD—I take it Dr. Hotz reported this case particularly because the foreign body was removed through the wound entrance. The only successful case I ever saw where a foreign body was removed from behind the lens was one in which a piece of steel was removed through the wound entrance. In almost every case which I have seen, the eye was blind within a year afterward. This particular case was a piece about eight millimeters long and four thick, a piece of chisel that went straight through the center of the cornea. The case was sent at once, so that I saw it inside of an hour after the injury. The first time the magnet was introduced I got the click; the second time the steel came to the lips of the wound, and the third time I got it out. This was about four years ago, and the patient's vision in that eye is now about one-tenth. I have seen several cases where the eye has been saved, but there was no vision.

Dr. GRADLE—Among eight cases I have had two instances of success in removing steel from the eye. One was removed on the fourth day and could be seen distinctly with the ophthalmoscope. It was removed through an incision in the sclera. Two months later the vision was $\frac{2}{30}$. The second case was seen six months after the accident on account of failing vision. The foreign body was easily seen with the ophthalmoscope. Extraction with the magnet was easy and there was no reaction. Eight months later the vision was $\frac{2}{70}$.

Dr. WILDER—The results reported are brilliant, but such results encourage this operation altogether too much. Many cases of detachment of the retina, resulting from unsuccessful removal of foreign bodies, would not do nearly as much harm if left alone. If all cases of operation by the magnet were reported after the lapse of several years, we should find that the number of successes would be very small, certainly not sufficient to justify doing the operation as often as it is done. A positive indication for this operation is when the steel can be seen lying in the iris or lens, or in the vitreous. If the eye is quiet and the steel is firmly adherent, I see no occasion for an attempt at its removal, as nature will soon cover it with an exudate. To operate when the steel can not be localized, and only on the supposition that the foreign body is in the eye, seems to me injudicious.

Dr. TILLEY—Early in the history of this Society I exhibited two cases with steel visible in the retina. In both cases the eyes were quiet and there was some limitation of vision, but not much. I had one case in which the patient persisted that there could be no steel in the eye. I finally persuaded him to have the eye removed and there was found a piece of a cold chisel a little more than three quarters of an inch long.

Dr. MONTGOMERY—The only case of successful removal of steel which I have had was one in which I introduced the magnet through a new opening. The case came to me within an hour after the injury. The bit of steel could be seen with the ophthalmoscope. I made a section through the sclerotic and removed the steel without difficulty.

Dr. HAIGHT—I recently had a case where a piece of steel had remained in the eye for sixteen years. The eye was blind, but owing to the severe pain of the inflammation I removed the steel. The patient refused to have the eye enucleated.

Dr. FISHER—In my experience it has been very rare to retain serviceable vision after removing a piece of metal from the interior of the eye. This should not condemn the magnet, for when we have a piece of iron or steel in the interior of the eye

conservative surgery demands the removal of the metal or of the eye.

In regard to Dr. Tilley's case, I saw the first one at the time and also some eighteen months after he discharged it. A piece of metal was shining in the choroid, the media was clear and the vision was about one-half when he left Dr. Tilley. At the time I saw him the eye was in a very serious condition; the lens was opaque and there was a mild cyclitis. He refused enucleation. At the time Dr. Tilley discharged him, this might have been called one of the most hopeful cases of foreign body in the eye, yet the subsequent history shows how dangerous the leaving of such a substance is.

Dr. HOTZ—It seems to me that Dr. Wilder's position can not be sustained by clinical facts, if he says that the magnet does more harm to the eye than the foreign body, and that nature will cover the foreign body with an exudate to make it innocuous. I think it is a well known fact that nature does not do anything of that sort, as a rule, and that the foreign bodies in the posterior part of the eye, in the majority of instances, will destroy the usefulness of the eye and prove a source of danger to the other eye. The object of the magnet extraction of the foreign body from the eye, in the first place, is to save that eyeball for the patient, even if no sight is to be saved; for the blind eye, even with a detached retina, is certainly better for that patient than a glass eye; and, therefore, even if it were true that the disturbance by the magnet in the vitreous leads to detachment of the retina, that should not debar us from doing the operation, if we have a good prospect of preventing deleterious inflammations, cyclitis, etc., that the foreign bodies are apt to set up. To remove the foreign body, as the Doctor says, when it is located in the iris and lens, and in the vitreous only if it can be located with precision, is another remark which surprised me, because it is just in the iris and the lens that foreign bodies may remain a good while, and in the lens particularly, without doing any particular harm, except clouding up the lens, but not endangering the future of the eye.

I am far from encouraging the promiscuous operations, if I may so say, and I have taken opportunity in the past to discourage the use of the magnet for removing a piece of steel in the eye when an extensive cyclitis has taken place which in all probability will destroy the eye, whether the foreign body is retained in it or whether it is extracted. I advise the operation in the early stage, as soon as possible after the accident, especially before any inflammation has set in, and I do the operation, as I have said, in the first place, for the purpose of removing the cause of deleterious inflammation, to preserve the eye, no matter whether or not in that eye the sight will be restored. In the case I have reported, where the foreign body was lodged in the ciliary portion of the choroid, I think it would have been very risky, and on my part reckless, to leave the foreign body in its position, because in that vicinity it was bound to set up inflammation sooner or later that would lead to the destruction of that eye and probably jeopardize the other eye.

OPERATION AND AFTER TREATMENT OF CATARACT. PREPARATION OF THE PATIENT.

Dr. GRADLE—In order to minimize the danger of cataract operation, we should aim first to have the patient in the best possible state of health; secondly, to guard against avoidable infection. On the first subject I can state nothing but self-evident truths. If the patient has passed through any disease likely to interfere with his resisting power for the time being, it is to his interest to defer the operation. Cataract is not an operation of emergency, but one for which the time can be selected. If, therefore, he is in a condition at the time which may in any way endanger the success, delay is advisable. Thus the persistence of a severe cough, or any form of intestinal disturbance likely to prevent the quietude of the patient should cause us to delay. Whether in diabetes, so frequently a cause of cataract, we should delay the operation until we get the effect of an antidiabetic remedy, is perhaps an open question. The results of operating during diabetes have not been unfavorable on the whole, but it seems to me wiser to diminish any possible source of trouble by reducing the excess of sugar, for clinical observation has shown that diabetic patients are very liable to pyogenic infections.

Of more importance is the second division of our subject, namely, the combatting of any avoidable source of infection. The most important topic to which I can refer is purulent inflammation of the tear sac. Unless it is absolutely unavoidable, we should never perform a major operation on the eye while the tear sac secretes fluid. If there is no time for the cure of the condition, we must resort either to extirpation, or at least to temporary exclusion by completely closing the puncta with the canthary and assuring ourselves that they are absolutely closed.

In case of conjunctival disease, the operation should also be deferred until an absolute or relative cure is obtained and no further secretion exists. Blepharitis, too, should receive attention before an operation is attempted. At the time of the operation we should sterilize the skin and lashes by scrubbing with soap and water and any efficient antiseptic, so as to obtain as sterile a neighborhood as the general surgeon would demand. It is a different question, however, regarding the conjunctiva. Observations have shown that the conjunctiva, even when normal, has harbored germs, sometimes virulent germs. The observations by Gelpe have made it likely that the more normal the conjunctiva, the less is the probability of existence of pathogenic germs. This would indeed agree with clinical observations as to the danger of the operation. It has, however, been shown conclusively by Randolph, and by some continental oculists, that it is impossible to sterilize the conjunctival surface either by flooding with sterile fluids or with efficient antiseptics. The latter, especially corrosive sublimate, are not merely useless, but absolutely undesirable on account of the irritation to which they give rise. By reason of the secretion which they produce I would consider them a menace instead of a benefit. We must hence take our chances at present as regards infection from the conjunctival surface and simply avoid the possible infection from impure skin, soiled lashes, or infected instruments.

THE INCISION.

Dr. MONTGOMERY.—A proper knife is of the utmost importance. I prefer a knife whose breadth is at least two and one-half millimeters.

As to the incision itself, I began first with the Graefe modified linear, and used that for a number of years. Then I changed to one almost entirely in the cornea, but for the past eight or ten years I have made my incision just back of the limbus, including about one-third of the circumference, and terminating with the conjunctival flap. I use this incision whether for simple or combined extraction. It is essentially what is known as the old flap. My experience has been that we are not more apt to get a prolapse with this than with other forms of incision; and its great advantage is that we are more certain of a rapid healing of the wound, and it is the flap I consider of importance as coapting the cut edges.

IRIDECTOMY.

Dr. HORZ.—As a safe advice to beginners I should say, by all means operate with iridectomy, because that operation is applicable in all cases, because the delivery of the cataract is easier, and the removal of the cortical remains can be more thoroughly done after the iridectomy than through the intact pupil. I know it has been said that those who perform an iridectomy must give good and sufficient reason for justifying the mutilating of the eye. That is true; we should avoid mutilation if without it we can accomplish our object with safety and without taking any risks. Now, are there any advantages in the simple operation? The cosmetic advantage of the central round pupil counts for little. The eye is hidden by the thick glasses; it takes a close inspection to see whether the pupil of that eye is mutilated or not. I have never in my life heard a cataract patient complain of mutilation, or about any annoyance that could be referred to the iridectomy. The vision in the eyes operated upon with the iridectomy comes up to the same standard as in eyes with the simple operation. We have all varieties of vision in one class as well as in the other. That is about all there is to say about the advantages of leaving the pupil intact. But, on the other hand, we have always to fear prolapse of the iris, which happens to all operators; no matter how experienced an operator is he can not foretell in a given case whether it will happen or not; and if it does occur, the immediate excision of the prolapse will change the condition of the eye to that as if the iridectomy had been done at once; or if the prolapsed iris be not removed, it will set up troublesome inflammation of the eye and lead to unpleasant results. I feel much safer and easier at mind about the operated eye, when iridectomy has been done than when it has not been done, and therefore, as a rule, I adhere to the operation with the iridectomy.

For a while I have been a sort of an eclectic. After having made the incision, I let myself be guided by the behavior of the iris. If it remained quiet in the eye and did not prolapse at once, or if after the removal of the cataract the iris promptly slipped back into the eye, I abstained from iridectomy relying upon the sphincter muscle to hold the iris back in the eye if the wound should open again and the aqueous humor escape. That seemed to work in a number of cases very nicely, but sooner or later I had some bad results. In spite of all the good behavior the iris showed during the operation, on the next day in opening I found the iris protruding, and while

in some cases the excision of the prolapsed iris quieted the eye, in two instances it did not arrest the cyclitis, and the eye was lost; in one case it even necessitated the subsequent enucleation of the eyeball.

CAPSULOTOMY AND EXPRESSION.

Dr. BEARD.—In regard to the cystotome, I use a modification of the old Graefe instrument, the modification consisting in a change in the angle of the point and the rounding of the angular heel. The shank is straight and not malleable, and consequently the point rotates in a line with the handle. The introduction of the instrument should be done with the greatest care. Having pushed the cystotome, heel foremost, into the incision, passed it down flatwise between the iris and cornea until you reach the point where you desire to make the cystotomy, then turn the point toward the capsule, and make your incision quite extensive, the so-called peripheral cystotomy.

In the expression I use two spoons, one a flat one for depressing the lip of the wound, the other for coaxing out the nucleus. One must be careful not to press too long on the cornea and cause the lens to pop out suddenly, as the vitreous may follow. For the soft portions of the cortex left behind, manipulation with the spoon is often sufficient. If not, they may be removed with the handle of the spatula.

DRESSINGS.

Dr. WOOD.—(See Report of the AMERICAN MEDICAL ASSOCIATION for 1897.)

SECONDARY OPERATIONS.

Dr. WÜRDEMANN.—I find it necessary to do a capsulotomy in about six out of ten cases. The operation is done through the cornea by means of two needles, except where the capsule is very thick, when I use scissors. I have found it usually necessary to make but one capsulotomy. The needles should be sharp-cutting needles, those of Knapp preferred. A secondary operation is sometimes necessary for removal of cysts of the iris. These are preferably incised and compressed rather than cauterized.

C. P. PINCKARD, Secretary.

SELECTIONS.

Uncommon Form of Idiosyncrasy Contra Asparagus.—Among the curiosities of medical literature are the stories, many of them well authenticated, of the peculiar susceptibility of some unfortunate individuals to certain odors and emanations. Among the substances which have been known to produce attacks of spasmodic asthma are roses, musk, tea, ipecacuanha, the odor of a cat, fried fish, the dust of oats, malt, rice, feathers, wool and that caused in the demolition of old houses. Dr. Eugene Deschamps has added asparagus to this long list. He has published a full clinical report of a victualer, over forty years of age, who suffers from severe spasmodic attacks of coughing whenever he attempts to prepare raw asparagus for the cook. He is arthritic and nervous. Twenty years ago he became a cook and remained so for a long time, but was temperate, and hence suffered little general ill health, except from slight anemia. From the first, however, he found that while trimming asparagus in the kitchen violent sneezing, coryza and running in the eyes set in. Within half an hour dyspnea followed, with cough and expectoration. All these symptoms used to vanish within an hour or two. Hence he managed to continue at work and rose to be chef in large hotels. But whenever he assisted the undercooks in dressing asparagus the fits returned worse than before. He now owns a restaurant. Last spring he helped his own cooks on a busy evening and plucked a few stalks of asparagus. The fits of asthma came on at once with unusual violence and he was ill for several days. There was free expectoration and much coryza troubled the patient for some time. Dr. Deschamps gave iodide and bromide, with morphin in infusions of senega, cocain and borax lozenges and inhalations of steaming solutions of marsh-mallow and poppy. Neither fever nor albuminuria was observed. The increase of intolerance of asparagus is remarkable, as the patient is better off in every respect than he was twenty years since, prosperous, contented and strong. He can peel onions, carrots, turnips and other roots with perfect com-

port, but after plucking a considerable amount of salsify, mild sneezing and coryza set in, but without dyspnea. He has all along been able to eat asparagus freely, as the meal is never followed by any of the troublesome symptoms. Dr. Deschamps dwells on hay asthma, and states that he has seen a marked case of ipecacuanha asthma, a disorder, as has been said, noted by other observers.—*British Medical Journal*.

The Doctrine of Leprosy and its Treatment.—Dr. E. Baelz of Tokyo (*Berliner Klin. Woch.*, 1897, Nos. 46 and 47), in regard to the transmissibility of leprosy, admits the possibility of contagion, but thinks that there must be a very intimate and long-continued intercourse; he lays special emphasis upon the fact that the disposition to leprosy is very sporadic. He does not think that the proofs offered by Blaschke, for the inoculation of Eastern Prussia by Russia, are sufficient; he combats the opinion that there is an immunity of Europeans, produced by former saturation, and now on the wane. The cause of the small degree of contagiousness is to be found in the fact that the greatest number of lepers are free from ulcerous processes, that therefore the bacilli are under the protecting cutaneous cover; there are, moreover, reasons for assuming that most bacilli degenerate in the ulcers. In regard to the spreading of leprosy in the body, the author assumes that there is first a latent focus somewhere, that it breaks into the vascular system and that then the germs are carried abroad. The author, among the various symptoms of leprosy, calls particular attention to a peculiar wax-like glitter of the skin. He considers the thickening of the nerve stems as one of the most important symptoms; in this respect, the nervus auricularis magnus, which may swell to the thickness of a lead pencil, is especially remarkable. The tendon reflexes were frequently found, by the author, strikingly exaggerated. As a diagnostic help the behavior of the leprosy macule to anilin rubbing-in may be of advantage; if a body is rubbed with a powder of fuchsin, methyl-violet, then covered closely with absorbent cotton, and if pilocarpin is injected into the patient, then the sound perspiring skin was colored, but not the leprosy non-perspiring places. The author can not admit that leprosy is independent of climate. Thus he found, in Japan, that fever and general symptoms were often absent; pain on pressure over the nerves was only observed in very rare cases; just as rare were diseased mucous membranes of the mouth, of the nose and of the rim of the larynx and skin ulcers. Also, the author can not admit a peculiar vulnerability of the leprosy parts and that leprosy as such leads to cachexia. Leprosy arises, according to the author, usually not through ulcerous processes, but through a simple resorption of tissues. In regard to therapy he mentions favorable results obtained by him by a combination of: 1. Local treatment with salve of salicylic acid, applied in a peculiar manner; 2. of very large doses of oleum gynocardiae; 3. of strong baths inflaming the skin. The salicylic acid is used as 20 per cent. salicylic acid—lanolin—vaselin, at the diseased places which have previously been rubbed with pumice stone. The gynocardia oil is administered in doses of 15 grams a day. The bathing treatment consists in the use of the hot springs of Kusatsu, which are distinguished by a very strong content of free mineral acids. In a full bath of 200 liters there are 440 grams of free mineral acid, 230 grams of sulphurated earths, 45 grams of sulphuric iron. Add to this a temperature of 45-53 C. Of these baths the patient takes three a day and then five for the period of a whole month or longer.

PRAGTICAL NOTES.

Rheumatic Origin of Chorea.—Moncorvo considers chorea the cerebro-medullary manifestation of rheumatic infection developed in a hysteric or neurasthenic organism. He has found antipyrin, exalgin, asaprol and analgen, derivatives of the aromatic series known to affect rheumatic infection favorably, very effective in permanently curing a large number of cases of chorea. His last eight cases were cured in eighteen to forty-five days with 3 to 8 grams of analgen in twenty-four hours. *Bulletin de l'Acad. de Méd.*, May 17.

Electuary for Gouty Rheumatism.—(G. Baccelli). Sodium salicylate, 30 grame; sodium nitrate and potassium iodid, aa 20 grams; colchicum oxymel, 100 grams; rob of lappa, 300 grams. F. s. a. A tablespoon morning and night in half a glass of alkaline water. Continue for forty days.

An Objective Tone-Measure is suggested by Panse, by determining the amplitude at the moment when the sound of the tuning-fork becomes inaudible. Personal tests with a number of forks of different makes resulted in almost identical figures.—*Munch. med. Woch.*, May 17.

Serotherapy in Rheumatic Iritis.—Boucheron has found Marmorek's antistreptococcus serum remarkably effective in fifty cases of rheumatic iritis. He considers it a valuable tonic for the nervous system besides its specific action. Small doses are best: half to one cubic centimeter a day. Fresh, acute cases are most rapidly affected.—*French Congress of Ophthalmology*.

Syphilitic Lesions in the Stomach are more frequent than generally supposed. They simulate clinically simple ulcer and exulceration, the secretions keeping up the morbid processes, from possibly a slight erosion, but they can be cured without surgical intervention, hence every case of ulceration should be investigated for syphilitic antecedents.—*Gaz. Méd. de Paris*, May 21.

Collodium in the Treatment of Pruritus Analis and Hemorrhoids.—According to Samways, painting the anus with collodium will cure the pruritus completely in twelve to fourteen hours, and also tend to reduce the size of external hemorrhoids if applied on a tampon. The one disadvantage is a sharp burning sensation for a moment, which can be obviated by painting with cocaine beforehand.—*Memorabilien*, May 7.

Traumatic Hepatoptosis has been rarely observed. It may occasion chronic peritonitis from compression or disturbances in the alimentary canal: meteorism, colic, fever from intestinal intoxication, etc., or even lesions in remote organs from the habitual coprostasis, such as cerebral hemorrhage. Hepatorrhaphy is indicated in recent cases, but if of long standing, palliative treatment is all that promises relief.—*Gazz. degli Osp. e delle Clin.*, May 22.

Nitrate of Silver in Acute Lobar Pneumonia.—Eight cases have been reported recently in Italy, all treated and promptly cured with five to fifteen centigrams of nitrate of silver in ten pills a day, decreasing to two-thirds the amount after the fever subsided, which occurred almost at once. The crisis appeared the second day, with complete recovery in five to twenty-five days.—*Gazzetta degli Osp. e delle Clin.*, May 22.

Stimulation of the Lactal Secretion by Abdominal Massage is urgently recommended by M. Schein, who has found it very effective in several cases of absent or defective secretion. The blood is to be coaxed away from the uterus to the breasts, and the manipulations proceed on the assumption of important anastomoses between the genital organs and the mammae.—*Wien. klin. Woch.*, No. 18.

Menthoxol, Camphoroxol and Naphthoxol are obtained by adding to a 3 per cent. oxygenated water, 1 per cent. menthol or camphor, or 2 per cent. naphthol. Camphoroxol requires 32 per cent. alcohol to dissolve it: the two others require 38 per cent. The three, undiluted, destroy the spores of malignant anthrax in three hours. Wagner recommends them highly after using them on 200 surgical cases in a 10 per cent. solution. The wounds healed rapidly and healthy granulations were hastened. The deodorizing properties of the oxols with their own pleasant odor, are special points in their favor.—*Therap. Woch.*, 1897, 48.

Orthoform in Gynecology.—Blondel has cured a number of cases of endometritis with laminaria soaked a week in ether saturated with orthoform. Fifty other cases were treated successfully with intra uterine drainage with antiseptic gauze dipped in glycerin, holding orthoform in suspension, which

allowed them to pursue their usual occupations. The orthoform prevents any pain, and also renders the curettement of the uterus painless, if applied on gauze an hour before.—*Bull. de l'Acad. de Méd.*

Ratings for Damages.—In negligence suits for the benefit of the widow and next of kin, a different method of assessing the damages prevails in England from that which is usual in this country. An illustration of the difference is furnished by a case tried on February 15, before Lord Chief Justice Russell and a jury. It was an action by the widow of a sailor to recover damages for the death of her husband, who was a seaman upon a steamship belonging to the defendants, and was washed overboard in consequence of the improper manner in which a portion of the cargo was stowed on deck. Instead of awarding a lump sum, representing the injury sustained by all the family, as would be done in New York State, the jury assessed the damages at £200 for the widow and £100, £100, £60 and £40 for the four children respectively.—*N. Y. Sun.*

Intestinal Occlusion Due to Lumbricoids.—Dr. E. H. Bartley reports a case of intestinal obstruction due to lumbricoid worms, simulating appendicitis. On opening the abdomen a ball of intertwined lumbricoids was found in the ileum, resting against the ileocecal valve and completely occluding the opening. An attempt to force the worms through was without success. As the appendix was swollen, edematous and intensely congested, it was thought best to remove it. The ileum was then opened by a small incision and about forty worms removed with forceps. The incision was sutured and the abdominal cavity cleansed and completely closed. All went well for forty-eight hours; then sharp pain was complained of in the left leg, which became very cold; gangrene set in and seven days after the first operation an imperfect line of demarcation formed about four inches above the malleoli. Amputation was performed at the knee-joint and the child made a slow but perfect recovery.—*Archives of Pediatrics*, April.

Remarkable Success of Static Electricity in the treatment of tuberculosis is announced by N. M. Wassilieff, who reports a number of cases, cured for four years, which he considers a sufficient length of time to establish the merits of his new treatment. The patient sits on an insulated stool with rounded corners, connected with one of the conductors of the machine by a metal tube. The electrode is held at a distance of one to two centimeters from his mouth, the metal part connected with the floor or earth by means of a metal chain. The patient feels a slight movement in the air, and he inhales this electrified air for five or six minutes. At first he feels a dryness in lips and neck, followed by a sensation of warmth in mouth and throat, and occasionally a slight transient dizziness. If there is much debility, sparks also are induced over the chest, with a metal ball on a rubber handle, or with the finger. These electric air inhalations are supplemented by an abundant, strengthening diet and pure air, if possible the patient continuing his usual occupations. No secondary effects were observed in any case, even with advanced heart disease. The report in the *Klin. Therap. Woch.* of May 31 contains several typical observations of severe forms of the disease, with bacilli in the sputa, terminating in complete recovery to date. The shorter the duration of the disease, irrespective of the severity of the lesions, the more rapid the cure. He also reports thirty cases of non-tuberculous affections of the respiratory organs promptly cured with this treatment, catarrhal, chronic bronchitis, etc.

Antiseptic and Therapeutic Values of Chinolol.—According to the *London Lancet* for April 30, chinolol has been widely employed as a powerful and convenient antiseptic, and it is said to possess very distinct advantages over other antiseptic compounds previously in use. It is a yellow powder of definite chemical composition, soluble in water, and containing a quinolin group

in combination with potassium and the sulphate radical. Its antiseptic, disinfectant, and deodorant properties have been determined with very satisfactory results by Dr. Klein. It is important next to turn its properties in practice, and on this important question Professor Hobday, of the Royal Veterinary College, has contributed an interesting and instructive paper to the March number of the *Journal of Comparative Pathology and Therapeutics*. His experiments related to dogs, cats, and donkeys. The internal administration of chinolol to human subjects has been tried by Dr. Cipriani, whose results were recorded in that journal about five months ago. In this communication the treatment of tuberculosis with chinolol administered by the mouth or injected locally was followed by a rapid and apparently permanent improvement. The summary of Professor Hobday's results is as follows: 1. Chinolol acts well as an antiseptic, disinfectant, and deodorant when used in certain proportions. 2. Its action is better marked when used as a lotion than when used as a powder. 3. The powder is not suitable for use on fresh wounds unless diluted in some way or other. 4. For the disinfection of instruments care must be taken not to make the solution too concentrated. With instruments care must be taken, Professor Hobday finds, that the solution should be of the definite strength, as otherwise the instruments lose their edge and the handles become discolored and rough to the touch.

The Value of Green Vegetables and Levorotatory Sugars in the diet of diabetics is announced by Professor De Renzi, based on an "infinity of researches and observations," possibly the most important contribution to the cure of diabetes mellitus since Munson's articles in the *JOURNAL* (xxvii, pp. 872, 922 and 1072). He confirms Kütz's statement that diabetics assimilate levulose easily and that the levorotatory sugars in general are much more easily burned in the organism than the dextrorotatories, and advocates green vegetables for food, as they contain a kind of starch which is transformed, not into dextrose, but into levorotatory sugar in the organism, and neutralizes the effects of meat and fat ingested. The sugar and acetone vanish from the urine, if green vegetables are eaten exclusively for a day or so, and prevent their appearance if combined with a mixed diet. He has even found that a diet of green vegetables will prevent glycosuria in dogs after removal of the pancreas, and cure it if it has already appeared. The vegetables may be boiled or eaten in salads; cabbage, chicory and endives were the most frequently used in his tests, but all are effective: lettuce, asparagus, spinach, cauliflower, etc., although he warns that green peas and beans must be very fresh and the daily amount not exceed one-fourth kilogram. In the severest "carnivorous" cases he restricts the diet to the green vegetables alone for two days, but then, and in "amyliovorous" diabetes, allows a mixed regimen, including 100 grams green vegetables, 300 grams meat, 5 eggs and 500 grams red wine a day. No sweetening substance is permissible except levulose; saccharin, etc., are "foreign substances" and injurious. On account of the levorotatory sugar in fruit, this is also to be recommended in moderation. He has established the following daily limits for grave cases: Almonds, filberts, oranges, 500 grams net; mandarins, 4 to 8; pears and apples, one-fourth kilogram; plums, strawberries, 500 grams gross; peaches, apricots, 100 grams net; cherries, 200 grams gross. He ranks milk among the last substances to be allowed, although dishes cooked with milk are allowable in the first mixed diet. Diabetic patients, he adds, should take considerable active exercise. After ingesting a certain amount of carbohydrates they should take a walk, not a gentle stroll, but "with energy." Medication is worthless. Electricity exaggerates the decomposition of nuclein and causes sugar to appear in the urine. Mineral waters, massage, gymnastics are more useful, but the vegetable diet is the main thing, and it should be continued indefinitely and at least twice a year the patient should restrict himself almost exclusively to green vegetables alone for a few days.—*Gazzetta degli Osp. e delle Clin.*, June 5, 1898.

Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance	\$5.00
Foreign Postage	1.75
Single Copies	10 Cents.

In requesting change of address, give *old* as well as new location.
Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, JULY 16, 1898.

STUDIES OF THE GANGLION CELLS AND THE
CHANGES THAT OCCUR IN THEM IN GEN-
ERAL DISEASES AND OTHER
CONDITIONS.

During the past few years observations have shown the marked superiority of the NISSL method of staining ganglion cells. Many claims have been made regarding the significance of the changes brought out by the new stain, but it has not yet been made possible to correctly interpret the variety of the changes revealed.

Dr. JAMES EWING¹ recently read a paper before the New York Pathological Society, in which he sets forth the results obtained by him in a systematic examination of the ganglion cells of the central nervous system in a series of cases representing a variety of conditions.

After having tested a large number of fixing agents recommended for the preservation of the structure of the ganglion cells, EWING finds no agent is probably superior to alcohol, in the strength of 95 per cent. or absolute, as originally recommended by NISSL. He finds the following simple procedure as good as any: Stain the sections for one or two minutes in a 1 per cent. aqueous solution of methylene blue, gently heated; wash in water; decolorize in absolute alcohol; clear in oil of cajuput, and mount in Canada balsam.

EWING concludes that the so-called chromatic substance in the human ganglion cells is invariably arranged in a network with nodular thickenings. In Purkinje's cells the chromatic threads are much thicker than in the cells of the spinal cord and cere-

bral cortex. There is a cytoplasm with acido-philic tendencies, in which it is thought there may occur important changes, the evidences of which, however, are not yet demonstrable by the present methods. Of the radiating rows of oxyphile granules, described by HELD in connection with the axis cylinder processes, EWING found only indistinct traces. In the thinnest specimens that could be secured this area appears granular, but the granules are usually distributed irregularly. The reticular part of the cell body is surrounded by a rim of finely granular oxyphilic cytoplasm, which has a very distinct and abrupt line of demarkation. This is best demonstrated in freshly teased specimens. In all probability the substance of the axis cylinder process fills in the meshes of the reticulum of the cell body, and if this be true then the oxyphilic cytoplasm furnishes the material which undergoes pigmentation and other degenerative changes, and then the essential lesions that lead to loss of function of the nerve cells are to be sought for, not in the chromatic reticulum, but in the cytoplasm. This conclusion has already been reached by HELD and by APATHY, working with an entirely different technical method.

As regards the postmortem changes, EWING found that the earliest ones consisted in a diffusion of the chromatin throughout the nucleus; in certain cases the nucleus was shriveled and irregular. The chromatic reticulum of the cell body may undergo a granular splitting up, so that the cell becomes uniformly granular; vacuolation is also a constant and sometimes prominent feature. Similar changes may affect the dendrites. No uniform sequence can be given for the occurrence of the postmortem changes.

EWING then examined ganglion cells from cases of pneumonia, typhoid fever, and a number of other infectious diseases; also from auto-intoxications such as uremia, eclampsia, diabetic coma, sunstroke, from cases of acute poisoning by alcohol, morphin, carbolic acid and hydrochloric acid, and in a number of miscellaneous instances, including disturbances of the cerebral circulation, such as thrombosis and hemorrhage.

From these observations it is learned that virulent toxins may not cause any changes in the nerve cells demonstrable by NISSL's method, that the chromatic reticulum is comparatively resistant to the action of many bacterial poisons. In some cases of rapid septicemia, experimentally produced in the rabbit, bacilli were found in the interior of the ganglion cells, which nevertheless showed only slight evidences of degeneration. It is thought that any changes that may occur are not so much due to the direct action of the circulating toxins, as to the loss of function in the cell processes or to loss of blood supply in minute foci. The intermediate lesions may be referred to local circulatory disturbances, such as edema, capillary hemorrhages, thrombosis, obstructions to the lymph cir-

¹ Studies from the Department of Pathology of College of Physicians and Surgeons, N. Y., Vol. v, 2, 1898.

ulation, and lesions in the nerve trunks. In those cases in which there had been extreme dyspnea and cardiac weakness before death the medullary nuclei, especially the tenth and the "nucleus ambiguus," suffered more than others, and these and related observations would seem to point to the possible influence of over-action and fatigue in determining the lesions in the ganglion cells. In such diseases as hydrophobia extreme and wide-spread lesions affecting all parts of the cells occurred. Chemical poisoning may abolish nervous function without many demonstrable changes in the nerve cells. When the action of the poison is prolonged at least twelve hours, however, changes may be produced in the chromophilic substance, as would indeed be expected from the experimental study of the effect of various poisons upon animals.

In the acute lesions it concerns a process of chromatolysis, which may be of the same character in various groups of cases, although distinct stages may present different appearances. When the lesions are ascribable to local anemia the changes consist of a uniform granular appearance of the chromatic substance, which may be fine or coarse, depending upon the stage of the process, all ending in the same complete loss of nodal thickenings with more or less preservation of the reticulum.

Among the changes in the nucleus those of the nucleolus are to be mentioned. The nuclear network may be granular and irregular or entirely absent. Vacuoles and granules may occur in the cytoplasm.

EWING found that there was no specific features in the appearance of the cells in the fatal cases of alcoholism, tetanus, and thrombosis of the basilar artery: the principal occurrence was chromatolysis. This process may occur without distinct change in the nucleus. EWING believes that further degeneration frequently occurs after chromatolysis is complete, because there may be entire absence of changes in the nucleus in the cells with preservation of the reticulum of the cell body, with functional activity, as can be demonstrated in over-heated rabbits. EWING has repeated the experiment of GOLDSCHIEDER and FLATAU of subjecting rabbits to high temperatures, and he has found that the chromophilic bodies of the anterior horn cells may be largely obliterated, and yet the rabbits may be running actively about the laboratory.

He concludes, first, that the chromatic substance of the nerve cell is more susceptible to the influence of disturbed circulation than to the action of virulent bacterial toxins.

Second, that LEVI's observation is of great significance, if this can be verified, namely, that during hibernation chromophilic bodies disappear.

Third, that the relation of the chromatic substance to the activity of the cell still remains a matter of conjecture.

Fourth, that in the premature, and even in the full-

term infant, chromophilic bodies have been found to be absent or but imperfectly developed.

Fifth, that chromophilic substance of the ganglion cells probably represents a state of physiologic nutrition, which may vary between the full development of such bodies to their complete absence as in the motor cells of hibernating animals.

Sixth, that while the chromatic substance of the ganglion cells may be much diminished without real degeneration of necessity being present, yet it is certain that acute degeneration of the ganglion cells is usually evidenced by various forms of solution of the chromatic substance.

It seems we are still far from a systematized knowledge of the real pathologic histology of the ganglion cells. The impression is gained from EWING's study that until it becomes possible to demonstrate the delicate morphologic or chemic changes in the cytoplasm and the intermediate substance of the cell, the key to this branch of pathology will not be grasped.

OUR INSPECTION OF SPANISH HOSPITALS IN CUBA.

While making a brief inspection of the general hospitals in the Province of Santiago, Cuba, we were so much impressed with the excellence of the management, the fine discipline and the care manifested in the details of treatment that we can not refrain from publicly testifying to the efficiency of our medical brethren in the service of Spain. Our inspection was made through the medium of certain reports and returns which, instead of being in the hands of *Excmo. Sr. Inspector de Sanidad Militar de la Isla de Cuba, Habana*, to whom they were forwarded in accordance with Army Regulations, are now by the fortune of war, on file in the War Department of the United States, Washington, D. C. From these we learn that the general hospital at Holguin, the Military Headquarters of the Province, is one of considerable size, having a capacity of probably 1500 beds, for there are fifteen ward prescription books, 12 medical, 1 surgical and 1 for *Senores Oficiales* or commissioned officers, and some of these wards as shown by the series of prescriptions have as many as 112 beds. The average daily occupancy of the hospital during the month of December 1897, was 700 patients. All the reports and papers examined were intended to be rendered on printed forms, but it is manifestly an understood thing in the Spanish medical service that the absence of blanks does not constitute a valid excuse for failure to make reports, as several of the complicated forms were ruled by hand. All were written with the utmost care to insure legibility, with the exception of the signatures of the medical officers, which are generally illegible although written with care and with elaborate flourishes above, beneath or around, as an integral part of each. These intricate pen-traced additions to the sign manual were

no doubt intended to give dignity and individuality, but to the practical common sense of the average American they are schoolboyish in the extreme. All are free from blots or erasures, and are clean, if we except the ward prescription books, which bear evidence in finger markings and other excusable soils of having been carried from bed to bed and thence to the dispensary. All the forms are printed in single sheets, those used during the month being stitched together in a printed or hand-lettered cover to constitute the report for that period.

The *libreta*, or prescription book, of each ward shows the quantity of each medicine prescribed for each patient at the morning and evening visits, and the entries of each visit are closed and certified to by the signature of the chief of the clinic. These entries are of interest as throwing light on the character of the cases and the treatment adopted by the officers in charge of the various wards. An extensive materia medica is employed, over three hundred different preparations having been prescribed during the month. Quinin in various forms, antipyrin, jaborandi and limonada vegetal occur with great frequency. Sulphate of quinin is usually written *sulfo. qq^a*. *Leche de vaca*, or cow's milk, appears in prescription as a medicament. The summing up of the quantities prescribed daily in the wards acts as a check on the pharmacist who renders a report at the end of the month of the quantities, and cost of each article sent out of the dispensary. The cost of the medicines used in all the wards during the month of February 1898, amounted to \$2,998.35. Wine of quinia was the costliest item, 977 kilos costing \$655.95. Among others we may cite wine of quinia and iron 197 kilos, \$109.88; disulphate of quinia 8529 grams, \$290.83; valerianate of quinia 1308 grams, \$46.04; limonada vegetal 790 kilos, \$28.48; acetate of lead 40 grams, 1 cent.

The next paper examined was a report of the official remedies compounded in the pharmacy, thus accounting for the constituents employed, as of sugar transformed into syrups and of alcohol into tinctures, etc., all of which have afterward to be taken up and accounted for. One would think this a satisfactory system of responsibility and accountability without a report showing the quantities of remedial substances, simple and compound, consumed on each day of the month. Nevertheless, such a report is rendered as corroborative of the totals for the month when verified by the daily prescriptions.

The next report examined was one, forwarded in triplicate, of articles purchased for the subsistence of the patients during the month of November 1897. It gives the name and address of the person from whom each purchase was made and the items, with certificates as to the current market price. The expenditures for the month amounted to \$24,819.52. Some of the items and prices may be of interest: 7700 kilos of fresh beef at 87 cents per kilo, the heaviest item in

the bill, \$6,699.00; 1600 kilos of chicken at \$1.25; 228 kilos of coffee at \$1.10; 4125 kilos of milk at 43 cents; 5470 eggs at 10 cents each; 3750 liters vino tinto at 25 cents, and 513 liters vino generoso at \$1.65. Another report in duplicate gives, classified by regiments, the name, company and rank of each patient, with date of entry into and discharge from the hospital, to show the claim of the hospital for subsistence and for an allowance for tobacco at the rate of 40 cents per man per month.

We examined also some annual reports from the General Hospital at Gibara, which is a seaport on the northern coast, about 20 miles from Holguin, all of which showed the same precision in matters of detail. This hospital is much smaller than the other, as its average number of occupied beds was only 100. Lastly, from the General Hospital at Puerto Padre, we found a series of reports purely medical giving all the cases under disease headings for the year 1897. Puerto Padre is on the north coast west of Gibara, and about 40 miles northeast of Holguin. These reports give all the items of information called for by our United States Regulations; name, rank, company, corps, age, nativity, occupation, dates of entry into service, of the beginning of the sickness, of admission into hospital, of discharge from hospital, cured, dead or invalided to Spain, and the number of days stay in hospital under treatment. Thus, under the heading of *Paludismo*, there are recorded 1726 cases, of which only 1 proved fatal; of *Fiebre amarilla* 64 cases, 26 fatal. The latter disease began in August, and was in full progress on Dec. 31, 1897, when the report closed. On the sheets for typhoid fever, pneumonia, tuberculosis, smallpox, venereal disease and syphilis, there is only the remark *Ninguno*, equivalent to "no case admitted during the year."

Whatever may be our views of Spain from our present inimical standpoint, we must confess that the glimpse we have obtained of Spanish medical methods as practiced in the hitherto obscure outposts of Holguin, Gibara and Puerto Padre, has given us a high opinion of the Medical Department of the Spanish Army.

THE NEWS FROM THE FRONT.

No formal report has been received at the office of the Surgeon-General of the Army from Chief Surgeon POPE of the 5th Army Corps at Santiago, Cuba, but some idea of the work accomplished by the medical department of that corps may be gathered from the Associated Press and other dispatches from the front. The health of the troops on the voyage from Tampa, Florida, was excellent, only 1 per cent. having been sick. After landing at the Juragua wharf and getting into position on Cuban soil the first excitement in medical circles was occasioned by the dash of the dismounted Rough Riders and Regular Cavalry, June 24 at La Guasima, in which Major FRENCH, surgeon

of the former, was reported as having distinguished himself by bringing in a wounded man from between the lines. The hospital corps detachment did its duty handsomely, collecting the wounded at the first aid stations whence they were moved by litter to the landing. Most of them were immediately transferred to the *Olivette*, which had acted as a field hospital for the corps during its voyage. All necessary operations and dressings were completed before 3 A.M. of the 25th. The main saloon was converted into an operating room, where the work was done by electric light.

After this several days were passed in making the needful arrangements for the attack on El Caney and the hill of San Juan, which took place on June 30 and was continued on Friday and Saturday, July 1 and 2. Here the losses were at first estimated at 400, but later despatches from General SHAFER stated that an underestimate had been made and that they would probably mount up to 1000; and still later press despatches indicated about 1800 as the number, a very heavy loss considering the small number engaged. Concerning Friday's fight it was said that the greatest care and attention were bestowed upon the wounded men. The hospital of the 2nd division was established on the field as was also that of General WHEELER's Cavalry Division, Major VALERY HAVARD, Chief Surgeon. The hospital of the 1st division was a short distance west of General SHAFER's headquarters. The ambulance companies proved very efficient and no wounded men remained on the field after dark. The cases were so numerous that the hospital canvas was insufficient to shelter them. Those coming in later had to be placed on the ground under palm trees in close proximity to the tents. Surgeons and nurses worked unceasingly for forty-eight hours to attend to them and prepare them for transportation to the landing. Medical officers from the fleet assisted the over-worked surgeons of the corps in their labors. Many of the wounded found their way to the base hospital, for one despatch says: The provisional hospital at Siboney received a large number of men who all night long loitered along the road from the front as best they could. Wagons conveyed many, but others preferred walking, and throughout the night the road was filled with the wounded who moved slowly along the path leading to the sea coast.

Attention has been called to two points, first, the small number of cases requiring amputation, and second, the small number of deaths among so many wounded men, and this latter notwithstanding the references made to the ghastly wounds caused by the brass jacketed Mauser bullet. Among the deaths was that of Acting-Assistant Surgeon DANFORTH of Milwaukee, Wis., who was attached to the 9th cavalry. Dr. DANFORTH is said to have been picked off by sharpshooters while attending to wounded men on the road to the rear. Several members of the hospital corps were wounded also in this way.

The division hospitals were amply supplied with field dressings and supplies, but on account of the unexpectedly large number of wounded the stock of hospital shirts, drawers, blankets, etc., ran short. Ordinarily in going into a fight soldiers throw away all their impedimenta or stack them in rear of their line of battle, so that blankets and knapsacks or blanket rolls containing spare shirts, drawers, etc., can be picked up anywhere, and as a matter of fact are picked up by the hospital corps men to be brought to the hospital with the wounded to eke out the hospital supplies; but as Dr. POPE had to telegraph his shortage of these we must suppose that clothing rolls thus thrown away by our troops in the recent battle must have been considered as treasure trove by our Cuban allies. Outside of these things the field hospitals lacked nothing, although we find two or three telegrams from Miss BARTON suggesting the amount of suffering assuaged by her efforts at the base hospital at Siboney. In one some elation is manifested at being under the direct fire of the Spanish sharpshooters, but it is not stated that this reckless exposure really took place during the truce. The work of the Red Cross has been mainly that of providing supplies from the *Texas* to the starving Cubans.

Ultimately as the operations were performed and the wounds dressed the wounded men were shipped off through the surf to the transports, the first of which, the *Iroquois*, arrived at Key West, Florida, July 5, with 320 sick and wounded. These, with the patients already there, fill all the accommodations at that place so that future arrivals will be landed at Tampa, where the hospital train is on duty. Meanwhile the Hospital Steamer *Relief* arrived at the front with ample supplies and a reinforcement of about thirty medical officers, among them Prof. NICHOLAS SENN. This handsome vessel has cot accommodation for 350 patients in the wards, and in case of necessity the hurricane deck may also be utilized for ward purposes. Full descriptions of the outfit of this ship have been given in most of the daily papers, including her baths, electric fans, search light and Roentgen ray apparatus, disinfecting chambers, refrigerating rooms, stills and carbonating machine.

CUMBERING THE RECORD.

The *Index Medicus* is a valuable publication that has as a special type and example of American medical journalism done credit to our country. It has also, in its complete bibliography of medical literature, introduced at least the knowledge of the existence of such a literature in this country into various quarters where it had been hitherto consciously or unconsciously ignored, and if at the present time there still exist those who consider American medicine still in its infantile swaddling clothes, we can, with the exercise of all needed charity, attribute such opinion to abnormal mental idiosyncrasy rendering them blind to facts,

to a wilfully maintained provincialism and prejudice. When all the world has to come to America to keep track of what is being done in medical publication, any wholesale disparagement of American medical progress comes with ill grace.

There is, however, a point of view from which there is perhaps some reason for criticism of American medical literature. No other country has such a multitude of medical serials, good and indifferent; and some of them, it is to be feared, falling under the category that is commonly sandwiched in between these two. It is not necessary to say what ones these are, and the reader may, if he so inclines, apply the suppressed adjective to any of the irregular publications that comes to mind. It is clearly impossible that all of these multitudinous publications can be kept at a high scientific standard, and equally so that their reason for existence can be the local demand for a high grade medical publication. Some few of them, and those often not the best, are financial successes, sources of income to their publishers, but this is sometimes the result of catering to a low taste in medical reading, filling up their pages with recipes and answers to correspondents whose ignorance indicates the type of their constituents, or they perhaps are trade journals issued in connection with some drug or medical supply house which with its facilities for advertising finds way to make them remunerative. A large number of the minor medical journals must of necessity make little more than their expenses, and this is sometimes considered as done by the addition of the subscription cost of their more valuable exchanges to the sum of the receipts. They are advertisements for their editors and sources of additions to their libraries, and while most of them are eminently respectable if not otherwise remarkable in their editorial conduct, their multiplicity and the stamp of provincial mediocrity set by a few of their number, and in a measure, upon the whole, has worked to the disadvantage of the reputation of American medical journalism. This is probably less true at the present time than in times past, and it may be said that when these serials really serve a useful purpose they do so by keeping up interest in medical matters by serving as the organs of local societies, and that they really are an indication of medical progress rather than of any unfavorable tendencies in the profession. This is certainly true to a large extent, but it does not do away with the fact that the same amount of energy, intellect and financial outlay, combined on a smaller number of publications, would have better results. It would certainly in that case do us more credit, for while there are European medical journals of no greater merits, they are not so numerous as a class, and are not accepted as setting the type of the medical literature as those in this country have been too often by foreign observers. The Chauvinistic European judges all by the worst and weakest, and in this he is very apt to be followed

by his imitators and admirers on this side of the Atlantic. The real merits of our minor medical publications are likely to be ignored for the single reason of their multiplicity.

The greatest evils, however, that we can attribute to this proliferation of medical journalism, are to be looked for in the overloading of our medical bibliography thus produced. It is clearly impossible for each and every local medical journal to keep itself filled with really valuable original articles, and were it so it would be hardly desirable. Many of them are ephemeral publications; their files are not to be found complete in any medical library, except it may be that of the Surgeon-General's office, and valuable matter contained in them would be practically lost to the world, at least so far as the possibility of original reference is concerned. This is in fact too much the case, and the remedy is not apparent under existing conditions.

Another evil which these so numerous medical journals favor, and one that also needlessly cumbers up our medical literature, is the custom that many reputable and prominent medical writers have of utilizing them for the republication in duplicate, triplicate or even quadruplicate of their articles. It gives their views and discoveries a wider public, it is true, but it would be better if this were attained by a more extensive circulation of a lesser number of journals. As it is, it is confusing to anyone engaged in medical research, and all the more so if, as is sometimes the case, the articles while practically the same are published in slightly modified form and with changes in the title. The *Index Medicus* is sometimes therefore on embarrassing guide in looking up the literature of a subject by reason of this undue cumbering of the record.

It is not to be understood from the above that any wholesale condemnation of the over-numerous medical journals of this country is intended. The fact that there are so many of them, however, weakens their influence collectively and individually, and the standing of American medical journalism suffers in the estimation of some whose judgment may not always be correct but yet has its effect. There are also some, it must be admitted, that are not exactly creditable representatives of their class and by the too common synecdochal method of certain critics they are considered as typical of the whole. In addition to this we have by reason of their existence the occasional practical loss to the world of valuable contributions and still more often the needless overloading of medical bibliography with titles duplicate or otherwise that will be forever practically inaccessible for original reference to the mass of scientific workers in medicine.

According to the *Index Catalogue* and the *Index Medicus* our country leads the world in medical bibliography. It is unfortunate that it also embarrasses it to so great an extent.

FURLOUGH THE CONVALESCENTS.

During the later years of the Civil War, it was found that our convalescent sick and wounded recovered faster when sent home on furlough, than when retained in hospital or convalescent camp.

Not only was the ever present element of home sickness eliminated by this practice, but the overburdened Medical Department was relieved of much care.

It is hoped that this practice may be renewed in case of our gallant Volunteers in this War.

CORRESPONDENCE.

What is to be Expected from the Surgical Treatment of Tubercular Lungs?

CHICAGO, July, 1898.

To the Editor:—In consequence of the surprising declaration of Dr. Murphy, that tuberculosis of the lungs can be cured by injections of nitrogen gas into the pleural cavity, the question arises, what may we expect of this measure, setting aside all the difficulties arising by impossible diagnosis of adhesions, which would in some cases make the injections inefficient. We will only consider cases in which the method would effect a total compression of the diseased lung. What will be the consequence of such a state, so far as known by pathologic observation?

1. It may be remarked that we know such cases, in which a healthy or emphysematous lung is compressed by rupture of some air cells, mostly in the place of a circumscribed adhesion of the pulmonary surface to the costal pleura. In general such traumatic pneumothorax heals without any difficulty.

2. If a tuberculous lung is collapsed by pneumothorax, occasioned by a rupture of its surface, mostly by infection of the pleural cavity by the contents of the ruptured parts, a pyopneumothorax is the consequence. But in many instances, this resulting pleuritic effusion may be very slight or totally deficient. The rupture heals and we have a simple pneumothorax, not very different from the artificial process proposed by the bold operator. These forms of pneumothorax can subsist very long in tuberculous patients. Is it observed anywhere, that under these circumstances the tuberculosis of the collapsed lung is healed or at least reduced? This question can only be answered by observation. So far as I can remember, I have never seen any signs of reduction of a simple or suppurative tuberculosis under such compression. The peribronchial knots, which are lying superficial, are protruding over the surface of the compressed parts and will not be reduced by exclusion of the air in the adjacent air cells. On the other hand, ulcerations of the bronchi or tubercular deposits in the walls of a cavity in the apex or elsewhere in the lungs, will not be under different conditions than they are in a respiring organ. Bronchi with cartilaginous walls and cavities with fibrous surroundings can not collapse, and will receive the same or a somewhat smaller quantity of air in respiration. The air included in these cavities may become somewhat richer in carbonic acid and poorer in oxygen, but this does not seem to be a healing factor, because quite the same composition of air will arise in every badly ventilated apex of the lungs. The proposition of Hanau is generally accepted, that the apex of the lung becomes the prominent seat of tubercular infiltration by insufficient ventilation, there being a normal condition and in a much higher degree in such persons with abdominal respiration. Every physician treating tubercular patients institutes regular gymnastics in such cases to promote deep inspirations and prolonged expirations under higher

pressure. If a change of respiration takes place in such cavities with solid walls in consequence of an artificial pneumothorax, it will endanger these parts and prevent healing of the tubercular process contained in them.

The artificial pneumothorax may influence the course of tuberculous processes favorably only in one respect by lessening the expectoration retained in cavities or bronchi. It may be that in this way also the spreading of tuberculosis into the inferior parts of the lung may be impeded, certainly for a short time and not definitely. Dr. Murphy is to be credited that coughing patients can sleep undisturbed by cough after the institution of the artificial pneumothorax, but it is questionable whether tubercle bacilli will die in the retained sputum and pus. At any rate, the surgeon would not consider such a retention of pathogenic organisms as helpful. On the contrary, we always search to eliminate such organisms and dying or dead cellular material. That tubercle bacilli and cocci will not die in such masses of pus, mucous matters and polynuclear leucocytes is shown by the vegetation of these organisms in the caseous tuberculous infiltrations. The destruction of these organisms is effected by certain forms of leucocytes, named macrophages by Metchnikoff, and we are glad if we can promote their appearance in the sputum, because their presence denotes the first sign of beginning salutary reaction of the body. I demonstrate this often to my pupils in the tuberculo-cidin treatment. This salutary change is directly hindered by the artificial pneumothorax, promoting not only atelectasis of the air cells, but effecting also anemia. The elastic tissue of the lungs absolutely closes all small vessels, if it retracts by the pressure of the injected nitrogen gas.

All clinical experience demonstrates that anemic condition of the tissues, and particularly in the lungs, is favorable to the development of tuberculous processes, if such germs are present. So Traube has shown that stenosis of the pulmonary artery is followed mostly by tuberculous lung affections. The same is the case in deformities of the chest, impeding the movements of the chest wall, as in lordosis and scoliosis of the spine. The process always commences on the side where the thorax is contracted. The flat chest, so often present in hereditary forms of tuberculosis, promotes the development of the disease in the apices of the lungs and hinders the process of healing. The same effect is produced by a weak heart, so often accompanying this malformation of the chest. Congenital aplasia of the aorta promotes anemia (Virchow) and later frequently leads to tuberculosis.

We observe quite the contrary in a state of increased blood pressure, as in well compensated cases of valvular destruction of the left side of the heart. After the first observation of Traube, who considered this condition as favorable in tuberculosis, I have during the past thirty years observed many cases of involvement of lung tuberculosis under this condition, but I know also, that if the compensation is destroyed, as it occurs often in advanced age, the old repressed tuberculous process can break out again, mostly in the form of tubercular pleuritis, the lungs being saved more as the pleura by the direct flow of the blood to them through the pulmonary artery, whereas the weakened left heart ceases to impart enough pressure to the arteries of the body. This fact, the limitation of tuberculous development under the effect of higher venous pressure, has been practically demonstrated in the treatment of tubercular knee-joints, by Bier, a pupil of Esmarch. This treatment, by the way, will only be effectual if the stagnation of blood is very limited, because higher degrees of venous stagnation impede the emigration of leucocytes (Cohnheim).

If one were to try to produce the most favorable condition of circulation in tuberculosis, by physical means, one should institute artificial destruction of one aortic valve, which I have first shown in dogs to be a very harmless operation, but I would not counsel its performance in men.

In Dr. Murphy's experiments with tuberculous individuals the higher blood pressure in the not operated lung can be favorable, but the effect will only be temporary, and dangers will not be excluded, such as ruptures and bleedings from the single respiring lung, which then has to sustain a higher pressure of circulation and respiration.

From all this I must conclude that the proposed treatment of tuberculosis of the lungs by an artificial pneumothorax can not be supported in any way by our present knowledge, but we may quietly expect farther communications from the side of the bold surgeon.

The question of partial or total extirpation of one lung, also developed in the short theses of Dr. Murphy, is one of the gravest problems of modern surgery and we must be very well satisfied that Dr. Murphy, as it seems, has vanquished many difficulties. But we must say, also, that the indications for these operations will only arise if the progressive tuberculous process has entirely subsided. Large cavities filled with non-tuberculous pus or extensive fibrosis with numerous small cavities would give good opportunities for such operations. Certainly it would be a very great progress in our science, if the surgical art would give us the opportunity of inspecting the diseased lung in the same safe manner as we can now do the organs of the abdomen.

EDWIN KLEBS, M.D.

Melancholy in a Leper.

NEW YORK, JUNE 6, 1898.

To the Editor:—Some time ago you published a letter of Dr. Hansen, in which he took occasion to assert that there is no such thing as *melancholy of a leper*. He said, with Norwegian urbanity, that the melancholy in question was an invention of Dr. Ashmead. Will you kindly publish, for the enlargement of the knowledge of this gentleman in matters of leprosy, the following case, reported by Professor Meschedes, Königsberg, Prussia. It is really too bad that Dr. Hansen, probably on the strength of his bacillary discovery, should have come to the conviction that in matters of leprosy, when he speaks the universe ought to listen with entire submission.

The gentleman from Norway preserved through the Conference of Berlin an attitude which is entirely in accord with such a conviction.

ALBERT S. ASHMEAD, M.D.

From a Report of Dr. Schlessinger of Vienna, Section of Neurology, International Medical Congress, Moscow, August 19 to 26, 1897.

Professor Meschedes: "I consider that leprosy exerts a direct influence on the development of dementia, the cerebral phenomena resulting possibly from some irritating lesions of the nervous system brought on by their toxins. I base this theory on a case of psychosis with which I have recently met in a leper. The patient, a man of 28 showed the first symptoms of leprosy in 1891. In December, 1896, without any obvious cause, he was suddenly attacked with symptoms of acute dementia which necessitated his admission into my wards. He was discharged in four and one-half months, having recovered from his mental affection, and was transferred to the medical wards to receive treatment for the leprosy itself. After a short initial period of melancholia, during which the patient refused to take food, hallucinations of all the sense organs suddenly developed, with excitement, oppression, intense motor discharges and delirious ideas of a religious nature. After a few remissions and an attack of megalomania, the mental phenomena gradually improved and finally disappeared entirely.

"We may note as constituting the peculiarities of this case, sudden explosive onset of the mental trouble and also the existence during the initial period, of evident symptoms of cerebral and cutaneous congestion. The skin of the face was particularly red and swollen, and the cutaneous sensation evidently constituted the main starting point of the hallucina-

tions. The patient fancied that he was being tortured; he felt a sensation of heat which he himself estimated to have been fourteen times higher than the normal body heat; there also existed a state of sexual excitement of unusual intensity and a disturbance of the muscular sense, which gave him the impression that his whole body was being lifted. The congested state of the skin subsided on parallel lines with the retrogression of the psychic disorders. The last hallucinations of the period of decline also manifested themselves in the sphere of cutaneous sensations; the patient had the impression that snakes were creeping round his legs.

"The predominance of tactile hallucinations, pleads, in my opinion, in favor of the hypothesis of a *direct action* of the leprosy bacilli on the nervous system.

"I may add that one of the patient's brothers had also suffered from dementia. No other member of the family had ever exhibited any psychic disorders, so that there can be no question in the case of an hereditary psychopathia, properly so-called, but a simple family predisposition to mental trouble. The question might also be asked whether the attack of dementia was not due in the case of the brother, to some *latent leprosy infection*."

Removal of Foreign Body from Trachea.

DENVER, COLO., JUNE 26, 1898.

To the Editor:—As I am under obligations to some of the members of the AMERICAN MEDICAL ASSOCIATION to report to them the progress and final results of the following case, I would like very much, with your permission, to use THE JOURNAL as a medium through which to reach those who became interested in the case during their attendance at the AMERICAN MEDICAL ASSOCIATION here in Denver.

History of case.—I was called May 8, 1898, to see George S., aged 12 years, and found him with temperature of 103 degrees, rapid breathing and a hacking cough, with occasional paroxysms of severe coughing, which would leave him almost exhausted. The mother informed me that he had swallowed a pin on May 25, 1898, and that he had coughed very hard ever since that date. By physical examination the presence of a pin in the left bronchus was diagnosed by the entire absence of aspiration sounds over the entire left lung and the sibilant sound heard near the bifurcation over the left bronchial tube. I decided that in place of swallowing the pin he had sucked it into the trachea and from there into the left bronchus, and advised an operation for its removal, but it was June 13 before I could get permission, on which date I performed inferior tracheotomy and found the point of the pin at the bifurcation and the head in the left bronchial tube. The pin was seized and removed by a long forceps. The head of the pin was covered with a thick mucopurulent matter which formed a plug that completely obstructed the bronchial tube. On removing the plug a free discharge of pus followed from the left lung. After the patient's head had been lowered for quite a while to facilitate the flow of pus, the wound was cleansed and dressed. Expectoration was rather free for the first two or three days. Temperature gradually subsided, and by the ninth day it was normal; cough and expectoration very slight. On the fourteenth day the patient was discharged cured.

In behalf of the X ray, I will say that it was tested three times in this case and each time failed to locate the pin.

A. J. HORN, M.D.

The Philippine Islands.

FORT WAYNE, IND., JULY 10, 1898.

To the Editor: The prospect that the Philippine Islands may come under American rule suggests a matter of interest to the medical profession. The population of the islands is large and the country is very slightly explored. It will become necessary to send from the United States a num-

ber of men who will aid the administration there and who must combine scientific attainments and a habit of accurate observation with an occupation that will recommend them to the favor of the inhabitants of the group.

It is obvious that the medical profession alone can furnish such agents. Missionaries would come into collision with the religious prejudices of the people and traders would not possess the requisite training to study the ethnology, natural history, geology, economics and diseases of the Philippines. An immense store of invaluable information would be collected by men working in a scientific spirit and located in the numerous provinces and districts of the islands, and they would more than pay the expense of stationing them by making a census and reporting on the habits and resources of the people.

An excellent plan would be to divide the islands into sanitary districts, with a medical officer over each. He would have medical charge of the district, and also would be required to report on the matters mentioned above, and on all others of interest to the government of the United States. The medical officers would soon be self-supporting, and would be found useful in representing the administration in their districts. There are lawyers holding most of the offices of the government and the medical profession is systematically ignored. But this is a favorable opportunity to secure recognition for the culture and administrative ability of American physicians. They would go to these lands not to plunder or oppress but on a merciful mission, and the whole world would be enlightened by the reports they could furnish, while the United States would be honored by the work they would do. This would be a new departure in colonial administration and its success would be sure to make other nations imitate it.

I hope that the practical members of the profession and the influence of the JOURNAL may be enlisted in support of this suggestion. I am very respectfully yours,

W. P. WHERY, M.D.

Picric Acid as First Aid in Treatment of Burns.

GRANITE CITY, ILL., June 28, 1898.

To the Editor:—The treatment of burns is as yet unsatisfactory, the death rate about the same and many remedies are lauded, but picric acid in solution has given me excellent results; therefore I wish to record several cases treated by this procedure.

Shock and septicemia are the most dreaded results from the more severe cases, but all this can be eradicated by the persistent use of a weak solution of picric acid.

During the past three years several cases have come under my care and all have been treated alike, much to my satisfaction. While I do not wish to be original in this sense I wish to recommend a good thing.

T. B. K., chemist, age 23 years, in opening a can of gasoline the escaping gases exploded, burning him frightfully about the body, face and extremities. He was carried to a building and when I saw him was suffering untold agonies. I immediately had prepared a saturated solution of picric acid and bathed the whole body in it, covering the body with cotton and bandages. After a few minutes he said the pain was all gone and fell into a sleep. Several others who got burned at the same time expressed themselves as relieved as soon as the solution was applied.

I generally make up a pint of solution at a time and dilute as wanted.

Picric acid	4 dr.
Alcohol	4 oz.
Water distil	8 oz.

Picric acid for burns of the first or second degree is the simplest, quickest and most satisfactory treatment in my hands. It deadens pain and allays suppuration, healing spontaneously, the only objection being its staining qualities.

I generally soak absorbent cotton and lay it smoothly on the wound, cover this with rubber tissue and leave it on for two days or until a new skin forms.

I also apply an ointment occasionally, composed of ichthyol and vaselin, which softens the hardened epidermis.

While I do not propose to bring out anything new in this modern treatment I hope at least it may be more often tried by those who have discarded the old fashioned methods so long employed on suffering humanity.

F. E. TULLEY, M.D.

Plagiarism.

MUNCIE, IND., June 23, 1898.

To the Editor:—In Vol. xxx, No. 24, page 1401 of the JOURNAL, under "Original" appears an article by Gilbert I. Cullen of Cincinnati, Ohio, which has the appearance of being original, and no doubt the writer wishes to convey that idea among the readers of the JOURNAL, as no credit is given any one for the thoughts or language used.

It is the boldest piece of plagiarism I have noticed for years. It is apparently taken in its entirety from the "Encyclopedia Britannica." The Werner Edition, 1895, contains every thought and nearly every sentence exactly as it appears in Cullen's article. The only difference is, that the encyclopedia contains a little more.

A man who will copy from an encyclopedia and publish the article in a scientific journal of medicine and surgery as an original article, should be exposed, and dishonor heaped upon his head. It is an imposition upon the readers of the JOURNAL and also upon the editor and publishers, as it tends to lower the high standing and dignity of the JOURNAL.

Respectfully,

F. E. HILL.

Etiology of Cerebro-Spinal Meningitis.

PARIS, ILL., June 27, 1898.

To the Editor:—I have been very much interested in recent reports and papers on cerebro-spinal meningitis, which I believe is caused by mold. Four of my cases were attacked after eating crackers that had molded and been warmed over by a grocer, and all have been in damp houses during damp weather. A great many cases occur in armies and among those who live in Alaska, where victuals are liable to be moldy. I notice that the straw used by the Third Illinois Infantry was damp.

Respectfully,

W. H. TEN BROECK, M.D.

Precocious Pregnancy.

INDIANAPOLIS, July 7, 1898.

To the Editor:—In reference to an article on page 42 of the JOURNAL for July 2, taken from the *Lancet* of April 23, I wish to say that I delivered a girl about June 1, at the age of 12 years and 10 months. The boy baby weighed seven and one-half pounds and is now doing nicely. The labor was normal in every respect; no forceps, no laceration, and an uneventful puerperium. This girl had menstruated several times before impregnation. She was not over-developed, and really not fully developed, there being little hair in the axillary or pubic regions. She is nursing her babe, though her breasts are small.

Sincerely,

WILMER CHRISTIAN, M.D.

P. S. I understand there was a girl 12 years of age delivered at the Women's Hospital, six years ago.

DES MOINES, IOWA, July 4, 1898.

To the Editor:—On Jan. 20, 1889, I was called to attend a case of confinement. On my arrival I found a girl 12 years and 10 months old in labor. After a rather tedious but uneventful labor I delivered her with forceps of a twelve-pound boy. The infant lived but a short time. The mother

had a normal puerperium. The mother of the girl was only 31 years of age at that time and had a daughter nearly four years older than the one confined. I am familiar with another case in which the mother was less than 13 years and 6 months old. I confined a girl in 1893, who stated to me that she had never menstruated and was less than 14 years old. This was afterward verified by her mother. She had no hair on the pubes, no enlargement of breasts or other signs of puberty.

Very truly,
L. DRAKELY ROOD, M.D.

BOOK NOTICES.

Abdominal Surgery. By J. GREIG SMITH, M.A., F.R.S.E. Sixth Edition. Edited by James Swain, M.S., M.D., etc. Two Volumes, 8vo, cloth. Pp. 1171. Philadelphia: P. Blakiston, Son & Co. 1897. [E. H. Colegrove & Co., Chicago Agents.] Price \$10.00.

"Less than a year had elapsed," says the writer, "from the publication of the fifth edition of this work when it became necessary to issue a sixth." The editor was actively engaged in the preparation of the fifth by abstracting literature, and the author recognized his assistants by requesting him to edit the sixth edition, but he had scarcely finished the first 100 pages when the death of the distinguished author occurred.

Little change had been necessary to make in the text except such as the progress of surgery has made necessary. The chapter on Hysteropexy has been rewritten.

It is altogether unnecessary for us to commend to our readers this masterly work. It is sufficient to say that the present edition is unsurpassed.

The first volume contains six sections, viz.: 1, Diagnosis of Abdominal Tumors; 2, Abdominal Operations Considered Generally; 3, Operations on the Ovaries, the Fallopian Tubes and the Broad Ligaments; 4, Operations on the Non-Gravid Uterus; 5, Operations on the Gravid Uterus and for Ectopic Gestation; 6, Operations on the Stomach.

The second volume contains eight sections, viz.: 7, Operations on the Intestines; 8, Operations on the Kidneys and the Ureters; 9, Abdominal Operations on the Urinary Bladder; 10, Operations on the Liver, the Gall-bladder and the Biliary Ducts; 11, Operations on the Spleen; 12, Operations on the Pancreas; 13, Unclassified Operations for Growths and Cysts in Omentum, Mesentery, Peritoneum and Parietes; 14, Operations for Abdominal Injuries; 15, Operations for Peritonitis and its Effects.

Text-Book of Physiology. Edited by E. A. SCHAEFER, LL.D., F.R.S., etc. Volume I. Pp. 1036. Edinburgh and London: Young J. Pentland. New York: Macmillan Company. 1898. [From A. C. McClurg & Company, Chicago.]

This work is intended to be exhaustive and to furnish in an accessible form the substance of the literature of the world bearing upon the subject, so as to render it largely unnecessary for the student of physiology of the higher class to consult original papers in foreign languages.

The first volume deals mainly with the chemic constitution and the chemic processes of the animal body and with those physical and chemic phenomena which are connected with the production and elaboration of the secretions and other fluids of the body. The work is thorough and well finished.

The contributors to this volume are: J. S. Edkins, M.D.; Arthur Gamgee, M.D.; W. H. Gaskell, M.D., LL.D.; Francis Gotch, B. Sc.; Albert Gray, M.D.; J. Berry Haycraft, D. Sc., M.D.; W. D. Halliburton, M.D., F.R.S.; Leonard Hill, M.D.; F. Gowland Hopkins, B. Sc., M.D.; J. N. Langley, M.D., LL.D., F.R.S.; B. Moore, M.A.; D. Noel Paton, M.D.; M. S. Pembrey, M.D.; E. Waymouth Reid, M.B.; W. H. R. Rivers, M.D.; J. Burdon Sanderson, M.D., D.C.L., F.R.S.; E. A. Schaefer, LL.D., F.R.S.; C. S. Sherrington, M.D., F.R.S.; E. H. Starling, M.D.

Uric Acid as a Factor in the Causation of Disease.—A Contribution to the Pathology of High Blood Pressure, Headache, Epilepsy, Mental Depression, Paroxysmal Hemoglobinuria and Anemia, Bright's Disease, Gout, Rheumatism and other Disorders. By ALEXANDER HAIG, M.A., M.D. Oxon., F.R.C.P. Fourth Edition with 65 Illustrations, pp. 698. Philadelphia: P. Blakiston, Son & Company. 1898. [E. H. Colegrove, Chicago Agent.] Price \$3.00.

This work first appeared in 1892, the second edition in 1894, the third edition in 1896 and the fourth English edition in 1897.

To those who believe that all ills in the human body, with a few exceptions, are due to uric acid, and "to be alkaline is to be happy," Alexander Haig appears as an enviable apostle and his book as the light of the world. We take pleasure in welcoming this new edition as embodying all the evil that can be said of uric acid and a thorough scientific demonstration of its baleful effects on the human body. To those not familiar with the work the book will be a revelation, not only on account of the undisputed facts which the author produces, but for the forceful manner in which they are arranged. That the work has passed to its fourth edition is plain evidence, if any were needed, as to the popularity of the work.

The Genesis and Dissolution of the Faculty of Speech. A Clinical and Psychological Study of Aphasia. By JOSEPH COLLINS, M.D. Pp. 432. New York: The Macmillan Company. 1897.

This work was awarded the Alvarenga Prize of the College of Physicians of Philadelphia, 1897.

It is an exhaustive monograph on the subject of aphasia and contains chapters on the history, general analysis and conception of aphasia, describes the different varieties under the head of motor aphasia, sensory aphasia, subcortical sensory aphasia, total aphasia and chapters on the diagnosis, etiology, morbid anatomy, treatment and medico-legal aspects.

This monograph will long stand as one of the most valuable contributions yet made on this subject.

A Manual of Hygiene and Sanitation. By SENECA EGBERT, A.M., M.D. Illustrated with 63 Engravings. Pp. 368. Philadelphia and New York: Lea Bros. Company. 1898.

This is a fair epitome of the existing state of the hygiene of the day with the exception of the chapter on quarantine, which, being taken from an unfair and misleading chapter on the subject in Rohé's Text-Book on Hygiene, is to that extent inadequate.

Transactions of the Section of Laryngology and Otology of the American Medical Association at the Forty-eighth Annual Meeting held in Philadelphia, June 1-4, 1897. Pp. 363. Chicago: American Medical Association Press. 1898.

This volume consists of reprints on extra paper of the papers read in the Section on Laryngology and Otology at the Philadelphia meeting of the Association. The volume is handsomely printed and it is needless to say that the illustrations present a better appearance than they do in the current number of the JOURNAL on account of the difference in the paper.

These Section books are becoming more and more popular each year, as they preserve in convenient form the special papers of the Section, without other matter.

The Johns Hopkins Hospital Reports. Report in Gynecology. 4to. Pp. 136. Baltimore: The Johns Hopkins Press. 1898.

The contents of this volume are: 1. A Critical Review of 1700 Cases of Abdominal Sections from the Standpoint of Intraperitoneal Drainage, by J. D. Clark, M.D. 2. The Etiology and Structure of True Vaginal Cysts, by James Ernest Stokes, M.D.

These high class observations are of great value to the medical profession and highly creditable to the authors. The possessor of a series of these reports, seven volumes of which have been issued, is to be envied as having at his hand a large share of all that is best in American experimental medicine and surgery.

Illustrated Skin Diseases. An Atlas and Text with special reference to Modern Diagnosis and the most Approved Methods of Treatment, by WILLIAM S. GOTTHEIL, M.D. New York: E. B. Treat & Co.

This work, three portfolios of which have been issued, will be issued in quarter portfolios, each containing 24 quarto papers, a text with numerous formulæ and four plates of cases from life, by a new photographic process.

The illustrations are accurate and numerous, and the plates are extremely life-like. We shall look for the succeeding portfolios with interest, and in the mean time compliment the author and the publisher on the splendid series so far presented.

Proceedings of the Dedication of the Hunt Memorial Building by the Hartford Medical Society, Feb. 1, 1898.

This volume, which is handsomely illustrated, contains pictures of Dr. and Mrs. Hunt; the building and its interior rooms; a poem by Mayer; the history and purposes of the building by Dr. Melancthon Storrs; the address on the occasion of the acceptance of the building by Dr. G. W. Russell; and the dedicatory address by Daniel C. Gilman, President of the Johns Hopkins University.

The volume concludes with the plans and description of the interior of the building and the list of members of the Society.

Yellow Fever, Clinical Notes, by JUST TOUTATRE, M.D., translated from the French by CHARLES CHASSAIGNAC, M.D. Pp. 206. New Orleans: *New Orleans Medical and Surgical Journal*, 1898.

This work while translated from the French was not published in France, but Dr. Toutatre who is a New Orleans physician wrote it in his mother tongue, being more familiar with that language than with the English, and his colleague, the accomplished editor of the *New Orleans Medical and Surgical Journal* has translated it.

It is a work giving results of thirty-three years of study, and observation of nine epidemics and it will be seen on inspection to be the work of a master.

A Country Doctor, by THOMAS HALL SHASTED, M.D., 1898, published by the author.

This book was originally published in the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* and two hundred and fifty copies have been printed, privately, for the author's friends. The sweet and simple story is charmingly told and the illustrations do not detract from the beauty of its English. Thousands of our readers enjoyed it when it was printed in the *JOURNAL*, and we refer those of our new readers who are not fortunate enough to possess a copy of the book, to the *JOURNAL* of Feb. 27, 1897.

Twenty-fourth Annual Report of the Secretary of the State Board of Health of the State of Michigan. Cloth. Pp. 723. Illustrated. Lansing. 1897.

This report covers the year ending June 30, 1896, is well printed and on good paper. A copious index adds very much to the usefulness of the volume, which is replete with data usually treated in such reports.

Proceedings and Addresses at a Sanitary Convention held at Detroit, Mich., Dec. 9 and 10, 1897. Paper. Pp. 160. Illustrated. Lansing. 1898.

This volume is a supplement to the report of the Michigan State Board of Health for 1898 and contains, among others, the following papers: "Germs; What They Are and how They Produce Disease;" "Isolation and Disinfection of Persons and Things;" "The Needs for and Value of Public Health Work;" "Popular Education in Sanitary Science;" "Diphtheria and Scarlet Fever, their Restriction and Prevention;" "Streets and Alleys and their Relation to the Public Health;" "Typhoid Fever and the Water-Supply of Detroit;" "Bicycling—from Social, Business and Healthful Standpoints;" "The Restriction and Prevention of Tuberculosis."

Transactions of the Vermont State Medical Society. 1897. Cloth. Pp. 224. Published by the Society, Burlington, Vt., 1898.

This volume contains the transactions of the annual meeting at St. Albans, Vt., Oct. 14 and 15, 1897, comprising the following papers: "Tumors of the Breast;" "Carcinoma of the Female Breast;" "Modern Management of Diphtheria and Croup Cases;" "Electrotherapeutics;" "Higher Medical Education;" "Osteitis Deformans;" "Paranoia;" "Significance of Post-climacteric Hemorrhages;" "Infantile Scorbute;" "Uterine Curette in the Country;" "Cancer of Uterus;" also the medical laws of Vermont, etc. The volume is a credit to the society.

PUBLIC HEALTH.

Health in Michigan.—The State Board of Health reports, for June, the five most prevalent diseases as rheumatism, neuralgia, bronchitis, tonsillitis, influenza. Compared with the preceding month, diarrhea, remittent fever and measles increased in prevalence, and pneumonia, influenza and pleuritis decreased.

Sterilized Lymph.—We are so used to the phrases "arm-to-arm vaccination" and "lymph direct from the calf," and to the preference shown to "fresh over stored lymph," that to most persons in England it would be a revelation to learn that no lymph is used in Germany until it has been kept four months under observation. Taken with the strictest antiseptic precautions, mixed with definite proportions of glycerin and sterilized water, the instruments and vessels being all absolutely aseptic, it is stored in sealed tubes and kept at fixed temperature until under the inhibiting influence of the glycerin, the extraneous microbes swarming in ordinary recent lymph have died out, the specific micrococci being unaffected and multiplying in the absence of other forms. This process of elimination of the foreign microbes and pure culture of the specific organisms occupies three or four months, and no lymph is sent out containing more than one or two harmless bacteria or torulæ in the cubic centimeter, most of the samples being absolutely free.—*Practitioner*.

Acute Primary Diphtheria.—The *Lancet*, April 30, comments upon the paper on membranous stomatitis of Dr. Juriât that appeared in this *JOURNAL*, March 19, and adduces a similar case reported in a French journal by Dr. Thiercelin. This latter case was regarded as one of true primary diphtheria of the mouth. The patient was an adult female who complained of pain on opening the mouth and had anorexia and a little fever. The lower surface of the tongue, which was not swollen, and the floor of the mouth were covered with a whitish-gray membrane. There were membranes on the cheeks, gums and lower lip. The disease did not extend beyond the pillars of the fauces. The submaxillary lymphatic glands were swollen, mastication was impossible, and intense fetor and salivation were present. Diphtheria bacilli were found in abundance in the membrane. M. Sevestre and M. Gaston have reported a series of cases of membranous stomatitis which constitute a special form, denominated by them "stomatitis impetiginosa." It attacked debilitated children, especially those recovering from measles or whooping-cough. A whitish adherent membrane similar to diphtheritic exudation formed. The tongue was rarely attacked. In nearly all cases the disease was associated with impetigo of the face. The staphylococcus pyogenes aureus was found in every case.

Actinomycosis of the Lungs.—Before the Berlin Medical Society, Dr. Karowski said the disease appeared in two forms. One of these, the catarrhal form, was due to the germs establishing themselves on the surface of the bronchial mucous membrane, the result being a chronic catarrh of the bronchi with actinomyces present in the sputum. The other form, the

destructive one, was of a much more serious character and presented three distinct stages, in the first of which the germs entered into the deeper strata of the bronchi, producing there a destructive peribronchitis. At first the illness is not attended by any well-marked symptoms and it may often be taken for tuberculous phthisis, but the absence of tubercle bacilli and the appearance of actinomycosis fungi in the sputum may establish the diagnosis. Moreover, the area of dulness on percussion is not at the apex of the lung, as in tuberculosis, but is below the clavicle. In the second stage the fungi have come from the lungs to the pleura, producing there a hemorrhagic exudation. A swelling of the thoracic wall as in empyema is very characteristic. The purulent accumulation may discharge itself either through the skin or through the diaphragm. In the third stage there are metastatic formations in different parts of the body, together with symptoms of general septicemia. These cases are hopeless. Dr. Karowski then showed a patient who had been sent to him for an alleged sarcoma of the pleura. There was well-marked dulness of the right side and by puncture the presence of actinomycosis was ascertained. An incision was made in the fifth intercostal space, a portion of the sixth rib was resected, the affected skin and muscles were freely removed, and the resulting large cavity was cauterized with Paquelin's thermocautery and dressed with iodoform gauze. The patient was profoundly collapsed after the operation, but eventually recovered. At the present time, three months after the operation, he still has a fistula, but actinomycosis fungi are no longer found in the discharge; the cough is only very slight and the patient has increased in weight five kilos (eleven pounds). Cases of pulmonary actinomycosis which have been successfully operated on are very rare, but would certainly become more frequent if an early diagnosis were possible.—*London Lancet*, April 23.

The Care for Revaccination in England.—Dr. Bond of Gloucester, England, has prepared for the Jenner Society a minute of the paramount needs of his fellow citizens for the stamping out of epidemics of smallpox. It is his belief that the experience of every recent English epidemic of that disease in his country, shows conclusively that if we wish to protect the community against these increasingly frequent scourges, we must take as much trouble to promote revaccination as we have hitherto taken to promote infancy vaccination. So long as the public are led to believe, as they have hitherto, that vaccination in infancy is the only thing about which the State need take any care, so long will the epidemics of so called "vaccinated" adolescents and adults, and of unvaccinated or badly vaccinated children be the approbrium of our country. There is only one way of effecting this, and that is by requiring, so far as is practicable, every child who enters a school to be efficiently vaccinated, and that before it leaves school it shall be equally efficiently revaccinated. It is to the revaccination of her adolescent population that Germany owes the remarkable immunity from epidemics of smallpox which she has for the last twenty years enjoyed, rather than to her compulsory vaccination in early childhood. For it is the adolescents and adults whose early protection in infancy has become attenuated by age who are most exposed to the risks of smallpox. If we could secure their protection by revaccination at the end of the school age, as well as that of the children at the commencement of it, we need not trouble ourselves much about the infants. We have been misled in this respect by false inferences from the experience of Jenner and the early vaccinators. When infants were the chief sufferers, because the adult population was in a large degree protected by having had the disease, the discovery of a means by which these unfortunate little victims could be almost absolutely protected naturally led to an undue estimate of the value of infant vaccination, especially as its effects were assumed to be more lasting than they really are. But we have now to deal with altogether changed conditions. Where infant

vaccination is fairly well maintained, as it has been in Middlebrough, it is the adults who have not been revaccinated who are now the chief source of danger, a danger which can only be avoided by investing every young person with the same degree of protection which we have for the last half century conferred upon the greater portion of our infant population. These observations are germane to the position of our badly protected communities. The occurrence of a case of smallpox in one of our Southern camps of the army of invasion into Cuba, teaches us that we are ourselves "traveling on thin ice." It is all very well to regard the regular forces as practically immune against smallpox, but there is a host of camp followers, attendants, etc., over whom there is little official control, and in it is a mass of inflammable material only awaiting the horrid varicelous spark to light up an epidemic. The medical authorities at Washington would do well to declare what steps have been taken by them to protect the army and navy against smallpox.

NECROLOGY.

T. E. MURRELL, M.D., Professor of Ophthalmology in the Barnes Medical College of St. Louis, Mo., died June 26, at Denver, Colo., aged 48 years. Dr. Murrell was a graduate of the University of Maryland in 1873, and after two years of hospital work settled in Little Rock, Ark., where he established an excellent ophthalmic and aural practice, and won an enviable position in the profession. He was an active, scientific worker, contributing much to the Section on Ophthalmology of the AMERICAN MEDICAL ASSOCIATION. In 1890 he was elected Secretary of the Section, and three years later a Vice-President of the ASSOCIATION. In 1894 he accepted the chair of Ophthalmology in the Barnes Medical College, and removed to St. Louis. Two years later, he was compelled by failing health, to relinquish his work in that city, and since that time has resided at various points in the western States and Territories. His death was due to pulmonary hemorrhage.

WILLIAM HOWARD BAILEY, M.D., a man of much ability in many lines, died at his home in Albany, N. Y., June 24. He was born in Bethlehem, N. Y., December 28, 1825, his father being Dr. Solomon Bailey. After an academic education he was finally in 1853 graduated from the Albany Medical College and began practice in Utica, N. Y., but after a year or so removed to Albany, where he continued to reside until his death. He was most widely known for his activity in the New York State Medical Society, having been elected its President in 1881, after a service of ten years as its Secretary. Although a municipal reformer and sanitarian, with a membership in many societies his career became somewhat uneventful after 1887, when he retired to private practice.

JOSEPH M. TURNER, M.D., Transylvania, Ky., 1841, of Brooklyn, N. Y., died at the home of his son, the Rev. H. B. Turner, in Washington, Conn., July 2, aged 82 years. In 1844 he removed to Brooklyn, N. Y., where he practiced continuously for near fifty years. Three sons by first marriage, one a Brooklyn physician, and another son, a daughter and a widow, are his survivors.

WILLIAM H. PARKS, M.D., died at the home of his son in Reading, Mass., June 21, aged 75 years. He was an alumnus of the Castleton Medical College, class of 1847, and practiced for some years in Great Barrington, Mass.

DAVID B. NELSON, M.D., Harvard 1849, of Iaconia, N. H., died there July 5, aged 75 years. He was a war veteran, a widely known citizen, and leaves a widow, a son and two daughters.

LOUIS E. LIVINGOOD, M.D., who was lost from the French line steamer *La Bourgogne*, in a collision sixty miles south of Sable Island, Halifax, N. S., was a member of the staff of the Johns Hopkins University. He was thirty-two years old, a native of Reading, Pa., and a graduate of Princeton and the University of Pennsylvania Medical School. He was appointed to a fellowship in the Johns Hopkins University in 1895, and

last spring was made an associate professor in pathology. He was on his way to study at the University of Strasburg.

A. L. MICHAELS, M.D., Kansas City, Mo., died June 29, from inflammation of the membranes of the brain complicated with pneumonia. Born in Illinois in 1854, he was graduated from the normal school at Valparaiso, Ind., in 1872, and was Professor of Natural Sciences in that institution for two years. He then studied medicine at Louisville, Ky., and later took a post-graduate course at Starling Medical College. In 1894 he was appointed Professor of Electro-Therapeutics in the College of Physicians and Surgeons, Kansas City, Kans., which position he held at the time of his death.

WILLIAM H. DECAMP, M.D., Grand Rapids, Mich., died July 4. He was born in Auburn, N. Y., in 1825 and during the Civil War was commissioned surgeon of the First Michigan Regiment of engineers and mechanics, serving three years. In the Grand Rapids Medical Society as well as in the State Medical Society, he has filled the position of President.

A. E. FARNHAM, M.D., Pittsfield, Me., July 2, aged 42 years. —Aretus C. Haynes, M.D., Kansas City, Mo., June 29, aged 55 years. —H. C. Himoe, M.D. Albuquerque, N. M., July 3. —Peter Hooper, M.D., Philadelphia, Pa., July 1. —Edward D. McDaniel, M.D., Coy, Ala., died in Denver, Col., June 27, aged 76 years. —Samuel McNair, M.D., Kalamazoo, died at Elburn, Ill., June 30, aged 75 years. —H. R. Nichols, M.D., Osage, Iowa, June 23. —W. C. Glines, M.D., Norwalk, Conn., June 27, aged 73 years. —N. C. Cowgill, M.D., Logansport, Ind., June 28. —T. Archibald Taylor, M.D., Washington, D. C., June 30.

DEATHS ABROAD.—Cornelius Herz, M.D., according to the press despatches from London died at Bournemouth, Eng., July 6. He was born in Beaucou, France, September 3, 1845. His father was a German Jew, while his mother was French. His parents removed to England when he was quite young, but after a short time the family came to New York city. He was graduated from the College of the City of New York with the class of '64, and afterward received the degree of M.S., from his alma mater. After an apprenticeship in the hospitals of that city he was sent to Heidelberg to study medicine. He continued his studies at Munich and Vienna, and finally at Paris. He was poor and unknown, but brilliant, versatile and audacious, just the man to succeed in the French capital, and so, by giving lessons in English and French and writing for the French newspapers, he was able to go on with his studies and receive his medical diploma. In 1870 he became Assistant Surgeon-General to General Chanzy's Army of the Loire and for his services received the Cross of the Legion of Honor. The Franco-Prussian war over he returned to America and married in New York Bianca Saroni a cousin of the poet Heine. The couple having soon settled in California he appeared as a member of the San Francisco Board of Health. It was there also that he started on his career as an electrician, and founded the electrical works which are still the pride of the city. In 1877 he went with his family to Paris and started on a brilliant career. He overthrew the gas monopoly, and provided the main thoroughfares with electric light. He founded the leading electric journal of the world, *La Lumière Electrique*. He established the telephone system of France, organized the first electric exhibition that was ever held, and finally became associated with the Rothschilds in putting into practice the theory of the transmission of force by electricity. At the same time he rapidly became a great social and political figure in the Republic. He was successively raised from the rank of Knight of the Legion of Honor to that of Commander, and, finally, when he was only 40 years of age, to that of Grand Officer. And such men as Chanzy, Gambetta, Ferry and De Freycinet were his sponsors at each promotion. He just missed receiving the Grand Cross of the Order of SS. Maurice and Lazarus of Italy. Crispi signed his brevet shortly before he fell, and

Rudini, who succeeded him, canceled the letters patent, which are still in the archives of Consulta. For years his income was large, and his entertainments were princely, while his charming manners and magnetic personality made him a great social favorite. When in 1892 the Panama bubble burst, Dr. Herz went under, and was charged with being implicated in the scandal. When the exposures were first made he fled to London, but was arrested under extradition proceedings on a warrant from the French Government charging him with fraud and embezzlement. As he was confined to bed, he was unable to appear in court. The case was kept open, and he was continued under arrest in his bed from 1893 to 1896. By special act of Parliament the magistrate was permitted to attend his bedside and take testimony. The magistrate promptly declared that the charges were utterly invalid and scarcely deserving of notice, and Herz was released May 2, 1896. Meanwhile the French Government had instituted numerous proceedings against him and confiscated all his property. As he claimed that this was persecution and that he had been injured in name and health, he demanded of the State Department as an American citizen that it prefer a claim for \$5,000,000 against the French Government. The matter is still under advisement. Nordau is said to have called attention to many stigmata of degeneracy in Herz's person but the profession scarcely claims Herz, as at no time did he more than practice medicine as a minor specialty. He frequently expressed a contempt for its emoluments. —Leandro Urrecha, M.D., Madrid, a distinguished obstetrician. —Dr. Gustav, member of the Imperial Council and of the Chamber of Deputies of Austria, aged 59 years. —Johannes Alexander Garten, *privat-docent* of surgery in Leipzig. —Prof. Frederic Jacob Trier, Copenhagen. —Dr. Dezaneau, Angers. —Dr. Neudoerfer, *privat-docent* of surgery in Vienna. —Prof. T. Eimer, Tübingen. —F. A. De Zenker, professor of pathologic anatomy at Erlangen; "noted for his discovery of trichinosis in man." —Carl v. Rokitsansky, professor of gynecology at Graz, aged 51 years. —K. E. With, professor of internal medicine at Copenhagen. —Dr. Fr. Kretschy, lecturer on internal medicine in the University of Vienna, aged 50 years.

SOCIETY NEWS.

New Jersey State Medical Association.—At the annual meeting held in Asbury Park, June 28, 29 and 30, the following officers were elected: President, C. R. F. Fisher, Bound Brook; first vice-president, L. M. Halsey, Williamstown; second vice-president, William Pierson, Orange; third vice-president, J. D. McGill; corresponding secretary, E. L. B. Godfrey, Camden; recording secretary, W. J. Chandler, South Orange; treasurer, Archibald Mercer, Newark. We will publish a report next week.

Canadian Medical Association.—The thirty-first annual meeting will be held in Laval University, Quebec, August 17, 18 and 19, 1898. There will be the usual fare and a third rate, on the certificate plan. Arrangements made so that members' families may take side-trips at a trifling cost. J. M. Beausoliel, president; F. N. G. Starr, gen. secretary, 471 College street, Toronto.

International Association of Railway Surgeons.—The eleventh annual meeting was held in Toronto, Canada, July 6, 7 and 8, 1898, under the Presidency of Dr. George Ross of Richmond, Va. The following officers were elected for the ensuing year: President, Dr. Bruce L. Riordan of Toronto; treasurer, Dr. E. R. Lewis of Kansas City, Mo.; secretary, Dr. Louis J. Mitchell of Chicago. The vice-presidents of the Association are Drs. R. E. L. Kincaid of Bonham, Texas, James G. Hunt of Utica, New York; James L. Foxam, Huron, South Dakota; W. Gunn of Clinton, Ontario; Hugh H. McKnight of Hartford, Conn.; C. F. Leslie of Clyde, Kansas; Hugh M. Taylor of Richmond, Virginia.

The place of next meeting was left to the Executive Board to decide between White Sulphur Springs, Virginia, and Richmond, Virginia.

MISCELLANY.

Dr. Grandy is Made Surgeon.—Dr. Luther B. Grandy, a most prominent and popular physician of Atlanta, was recently appointed by Governor Atkinson surgeon of the Third Regiment, Georgia Volunteers. Dr. Grandy will rank as major and will have under him two assistants, each of whom will hold the rank of captain.—*Atlanta Constitution*.

Hospital Ship for Manila.—At the suggestion of Mrs. Greenleaf, wife of the surgeon-in-chief of hospitals in the field, the Red Cross League has undertaken to start the collection of \$300,000 for the purchase of a hospital ship for the troops at Manila. The plan is to raise this sum by popular subscription in all the States west of the Rocky Mountains and then present the ship to the government.—*Times-Herald*, Chicago.

Kindness to the Wounded War Horse.—With a view to avoid extreme suffering among wounded horses or mules on the field of battle, it has been ordered by the Major-General commanding the Army that a veterinary surgeon, or some other person detailed by the commanding officer, will accompany troops in an engagement, whose duty it will be to put an end to the agonies of all horses or mules that in his judgment are suffering to a degree requiring such action on his part.

Examination of Physicians to Fill Vacancies in Volunteer Regiments.—The Secretary of War has adopted the recommendation of the Surgeon-General that when a physician has been appointed by the governor of a State to fill a vacancy in one of the regiments mustered into the United States service, the physician appointed should be examined by a board of three physicians appointed by the governor and without expense to the United States. The certificate of this board that the candidate has passed a satisfactory physical and professional examination be accepted by the War Department as evidence of his fitness for the place to which he has been appointed.

The Physical Examination of Recruits.—Comments on the fine physique and splendid development of the men in the Volunteer Army have been of frequent occurrence in our newspapers owing to the strict examination to which the men were subjected prior to muster into the service. We referred to this subject in our editorial of May 7, showing how large a percentage of men who considered themselves fit to be soldiers were rejected by the recruiting officers of the regular army. It now appears that quite a number of volunteers with serious defects were passed at the examinations a few weeks ago, owing probably to the hastiness and feverishness of the mustering-in procedures. In the recent transfer of men from the line to the hospital corps to fill up the latter an examination into the physical condition of the candidates was required by regulation and in conducting these examinations the medical officers representing the hospital corps rejected so many and for manifest cause that the attention of chief surgeons of corps and divisions was invited to the subject with the view of eliminating from the ranks all men unfit for service on account of disqualifications existing prior to enlistment. This will increase the percentage of rejected recruits still further and will no doubt lead to greater care and strictness on the part of medical men on duty at recruiting stations and mustering camps.

Analysis of Water Supplies for Army Camps.—From Washington, D. C., we learn that if, in the establishment of camps of organization and instruction or other comparatively permanent camps, it is deemed necessary to have a sanitary analysis of the water supply made in the laboratory of the Surgeon-General's Office. Chief surgeons are authorized to forward samples by express to Deputy Surgeon-General Smart, Army Medical Museum, Washington, D. C., and are required to send a communication to the Surgeon-General, giving an account of the source and the sanitary surroundings of the water. Not less

than half a gallon should be sent as a sample. Care should be taken that the containing vessel is perfectly clean. Any vessel which requires chemicals to clean it should not be used. It should be cleaned by filling several times and washing with water from the source which is to be sampled. Wickered glass demijohns, otherwise unprotected or clear glass bottles, boxed with packing, should be used in preference to stoneware jugs or other vessels of opaque material. Care is suggested also that the corks used be new and clean, for a cork tainted with any oxidizable substance, particularly alcoholic or saccharine liquids, destroys the value of the water sample for the purposes of analysis.

Red Cross Literature.—The war is bringing forth a crop of booklets decorated with the Red Cross of the Geneva Convention. Two such have come to our notice during the past week. The first is a "Stretcher Drill" by Surgeon-Major J. J. de Zouche Marshall, of the 3d V. B. East Surrey Regt., published by permission of Her Majesty's Stationary Office. This is an excellent little manual of its kind, but there is no room for it in this country notwithstanding the recent expansion of our military forces, as the "Drill Regulations for the Hospital Corps," published by the U. S. Government for the use of the troops, answers all our purposes. It is to be observed that the latter suffers in no way by comparison with the new English production. We discarded the fixed sling several years ago and our regulation litter weighs only a little over sixteen pounds while that carried by the British Red Cross soldier weighs thirty-two pounds. The second is "Antiseptic Methods as Applied in Active Military Field Operations," translated from the French of E. Forgue, Surgeon French Army, by Professor Louis Bazet, President San Francisco Polyclinic, and published for the use of Sanitary Corps of the National Guard, State of California by direction of Colonel Wm. E. Hopkins, Surgeon-General. It insists on asepsis in the field at the first dressing and ambulance stations by the free use of boiled water.

Army Health Reports of Troops in the Field.—On inquiry at the office of the Surgeon-General of the Army we find that satisfactory reports for the week ending June 25, have been received from the Corps encamped at Chickamauga, Ga. From the 1st Army Corps the Chief Surgeon, Lieutenant-Colonel Huidekoper, reported that the three division hospitals have been completed, with cots for 150 patients in each, and are doing effective service, although they do not yet have their complement of Hospital Corps men as attendants. The reserve ambulance company has been filled up; and the reserve field hospital started in connection with it has been used as a receiving station and a training school for men transferred to the hospital corps from the line. The general health is excellent, less than 1 per cent. absolutely sick, and less than 3 per cent. when all the trifling cases excused from duty and held in quarters are included. Reports from Lieutenant-Colonel Hoff, Chief Surgeon of the 3d Army Corps, show a small sick list in most of the regiments, although many men have been taken upon this list on account of vaccinia in its ordinary progress. Three of the regiments have relatively a large number on sick report. These are the 1st and 2d Arkansas and the 1st Mississippi Infantry. The diseases are chiefly malarial, and their prevalence is referred to the exposures incident to a change to an elevated location in the case of men who came from malarial districts. Lieutenant-Colonel L. M. Maus, Chief Surgeon of the 7th Army Corps, Major General Fitzhugh Lee, commanding, reported that during the week ending June 25, the camps of the Corps at Jacksonville, Florida, were in excellent condition. The grounds are policed regularly, and ditches have been dug to carry off surface water. The sinks have been provided with half barrels, and tubs containing saw-dust are used as urinals. The water-supply is abundant and of excellent quality, from artesian wells. The bathing facilities are superior; shower

baths have been constructed under temporary frame shelters for all the regiments. No trouble has been experienced in this command about rations or cooking; Hunt and Buzzacott ovens have been provided for all the battalions. The health of the men continues good. Occasional cases of disease occur, such as diarrhea, colic and debility from relaxing climatic influences. Lieutenant-Colonel A. C. Girard, Chief Surgeon 2d Army Corps at Camp Alger, Virginia, reported that the deficiencies of supplies is gradually being remedied. The non-effectives have constituted 6 per cent. of the strength, chiefly due to vaccination. The prevalence of measles is abating. The water-supply is good and is becoming plentiful on account of the sinking of deep wells. The efficiency of the division hospitals is improving, and the ambulance companies are being filled up by transfer from the line; the hostility to these transfers on the part of volunteer officers and men is passing away.

Camp Notes From the Army Corps.—From the 2d Army Corps, Camp Alger, Virginia, it is reported that during the week ending July 2, the non efficiency from sickness constituted three per cent. of the strength. Typhoid fever seems to be on the increase, and is believed to be due to the use of well waters on the farms in the neighborhood of the camp. The deep wells of the regiments give a pure supply. Deputy Surgeon General Smart has been directed to make a careful inspection into the sanitary condition of the camp, giving special attention to the water-supply and to the etiology of cases of typhoid fever occurring in the command. Colonel A. C. Girard, Chief Surgeon, has issued an order for the daily instruction of volunteer medical officers, but it can not be carried out systematically, as Major John L. Philips is the only regular medical officer with him, and both are worked to their full capacity in organizing, equipping and attending to sanitary matters. According to Lieutenant-Colonel Maus, Chief Surgeon 7th Army Corps, the water supply of that Corps at Jacksonville, Fla., is from a system of artesian wells. It is pure, healthful and abundant, and although saturated with hydrogen sulphid when freshly drawn this speedily escapes after exposure to the air. Colonel Maus considers it as good as any that could be obtained anywhere, and does not think it necessary to send any of it to the Surgeon-General's office for analysis. Some difficulty has arisen about the disposal of excreta. It appears that the city authorities of Jacksonville objected to the pit system used in the Camp, whereupon the Chief Surgeon recommended that if it could not be disposed of by a crematory, it should be hauled to a convenient place on the main sewer where a suitable manhole is provided with a hopper and allowed to escape to the river with the city sewage.

A Temperance Order from Army Headquarters.—Major-General Miles, commanding the Army, has issued general orders under date July 2, 1898, enjoining commanding officers to restrict or prohibit the use of wines and beer in their camps, and urging example as well as precept upon all officers in the interest of health and efficiency. The orders read as follows:

The Army is engaged in active service under climatic conditions which it has not before experienced.

In order that it may perform its most difficult and laborious duties with the least practicable loss from sickness, the utmost care consistent with prompt and efficient service must be exercised by all, especially by officers.

The history of other armies has demonstrated that in a hot climate abstinence from the use of intoxicating drink is essential to continued health and efficiency.

Commanding officers of all grades and officers of the medical staff will carefully note the effect of the use of such light beverages—wines and beer—as are permitted to be sold at the post and camp exchanges, and the commanders of all independent commands are enjoined to restrict, or to entirely prohibit, the sale of such beverages, if the welfare of the troops or the interests of the service require such action.

In this most important hour of the Nation's history it is due

the Government from all those in its service that they should not only render the most earnest efforts for its honor and welfare, but that their full physical and intellectual force should be given to their public duties, uncontaminated by any indulgences that shall dim, stultify, weaken or impair their faculties and strength in any particular.

Officers of every grade, by example as well as by authority, will contribute to the enforcement of the order.

Organization of Ambulance Companies.—As showing the system of organization of ambulance companies for duty in connection with field hospitals in the army as a whole, the following regulations published from headquarters of the Seventh Army Corps, Gen. Fitzhugh Lee, at Jacksonville, Fla., on the recommendation of Lieutenant-Colonel Maus, Chief Surgeon of the Corps, may be cited: The personnel of each division ambulance company of this corps will consist of three medical officers, seven hospital stewards, three acting hospital stewards and 104 privates, which will be under the command of the ranking medical officer assigned to duty with it, who will be held responsible for its discipline, instruction and management. He will make requisitions on the chief surgeon of the corps for the necessary pouches, drill regulations and blanks. He will also submit requisitions for the necessary litters, camp equipment and ordnance supplies without delay to the chief quartermaster and ordnance officer of the division. Rations for the division ambulance companies will be drawn as ordered for line organizations. The division ambulance companies will be given daily instructions in marching, litter drill, loading and unloading litters, improvisation of litters, method of removing wounded without litters, placing patients on horseback, the use of the travois, two horse litters, the preparation and use of ordinary wagons and other vehicles for the transportation of the sick and wounded, ambulance drill, inspection and muster of the detachment, tent drill, packing, packing hospital and orderly pouches, and the clothing roll. Regular daily instructions will be given in first aid to the wounded and medical emergencies. Directions as to the scope of first aid and medical emergency instruction, will be submitted by the chief surgeon of the corps. An ambulance will report daily after surgeon's call at each regiment to remove to the division hospital all cases designated by the regimental surgeon for hospital treatment. Men who become injured or are taken ill after surgeon's call, and requiring hospital treatment, will be reported to the surgeon in charge of the division hospital, who will have them removed as soon as possible. Medical officers assigned to duty with each regiment will attend surgeon's call and those men undergoing treatment in quarters, render emergency aid when needed, prescribe for those not on sick report requiring medicine for slight ailments and look after the sanitary condition of the regiment. They will be furnished pocket cases, first aid packages, bandages, tourniquets and all medical supplies needed for the thorough performance of their duties; also one orderly and one hospital corps pouch. All assignments of medical officers, hospital stewards, acting hospital stewards and privates detailed for duty with the corps and division hospitals, litter-bearer and ambulance companies and regiments will be made by the chief surgeon of the corps. Departures from the assignments of medical officers and members of the hospital corps set forth above will be temporarily made by the chief surgeon from time to time to meet the exigencies of the camp or battlefield.

Assignments, etc., of Medical Officers.—To the 1st Corps, General J. R. Brooke at Chickamauga, Ga.; Majors Calvin H. English and John P. Dodge, Brigade Surgeons and the following Acting Assistant Surgeons: Gerry S. Drever from Chicago, Illinois, George K. Sims from Richmond, Virginia; Wm. H. Haskin from New York City; David Baker from Fort Thomas, Kentucky; H. A. Glatzmayer from the General Hospital at Fort Myer, Virginia, and Charles S. Stern from Hartford, Connecticut. To the 2d Corps, General William H. Graham, Camp

Alger, Virginia: Major Joseph K. Weaver, Brigade Surgeon. To the 3d Corps, General James F. Wade, Chickamauga, Georgia: Majors Frank Bruso and Charles M. Drake, Brigade Surgeons. To the 4th Corps, General J. J. Coppinger at Tampa, Florida: Majors Schuyler C. Graves and Samuel T. Armstrong, Brigade Surgeons; Lieutenant Carl R. Darnall, Assistant Surgeon, U. S. A., whose orders to join General Shafter's Corps have been revoked and the following Acting Assistant Surgeons: J. W. Donnelly, Stephen M. Long, D. T. Laibe, R. Fleming Jones and Robert Boyd. To the 5th Corps, General W. R. Shafter at Santiago, Cuba: Lieutenant Colonel Nicholas Senn as Chief Surgeon of the Operating Staff and Acting Assistant Surgeon Harry S. Greenleaf. To the 7th Corps, General Fitzhugh Lee at Jacksonville, Florida; Majors George B. Bunn, George R. Fowler and John R. McDill, Brigade Surgeons. To the 8th Corps, General Wesley Merritt, Philippine Expedition: Major Samuel O. L. Potter, Brigade Surgeon. To the General Hospital at Fort McPherson, Atlanta, Georgia: Majors Willis Z. McDonald, Brigade Surgeon. To the General Hospital at Fort Monroe, Virginia: Major Donald Maclean, Brigade Surgeon and Acting Assistant Surgeon Eugene H. Hartnett. To the Leiter Hospital at Chickamauga Park: Acting Assistant Surgeon Henry R. Carter, Jr., from New Orleans, Louisiana. To the General Hospital at Key West, Florida: Acting Assistant Surgeons Charles Boyd from Macon, Georgia, and Robert C. Eve from Augusta, Georgia. *Resigned.*—Major Otis H. Marion, 6th Mass., Infantry Volunteers. *Nominations.*—Charles P. Pollard of Alabama as Assistant Surgeon of the 5th Regiment Volunteer Infantry; George E. Lyon of Missouri as Surgeon of the 3d Regiment of Volunteer Engineers and Julius R. Shnelke of Wyoming, and John H. Gibbon of Pennsylvania as Assistant Surgeons of the same regiment; Walter D. Webb and Charles I. Proben of New York as Assistant Surgeons of the 1st Regiment of Volunteer Engineers. *Nominations confirmed.*—Wm. W. Purnell of the District of Columbia and Joseph L. Bell of Illinois to be Assistant Surgeons of the 8th Regiment of Volunteer Infantry, and Julius A. Schnelke of Wyoming to be Assistant Surgeon of the 3d Regiment Volunteer Engineers.

The Field Medical Service of the Second Army Corps.—Lieut.-Col. A. C. Girard, chief surgeon, Second Army Corps, Camp Alger, Virginia, explains the contemplated work of the Medical Department as follows:

The Medical Department in camp.—The largest unit of hospital administration is to be the division hospital; if a brigade is separated permanently it will be a brigade hospital; if a regiment is separated permanently it will be a regimental hospital. The regiment in camp is entitled to one medical officer, one hospital steward, one orderly and one orderly for each medical officer, to carry the pouch, when on duty. The orderlies are detailed from the hospital company at the division hospital and for greater convenience should be assigned to the regiment for rations. The other medical officers and hospital stewards of the regiment do duty with the regiment unless detailed by the division commander, on the recommendation of the chief surgeon of the division, with the field hospital. The usual duties of regimental medical officers are: Attending sick call and sanitary duties. The senior medical officer will prepare the morning report of sick for the adjutant of the regiment and send a copy of it to the brigade surgeon.

For the purpose of caring for the sick in quarters with the regiment the government provides medical chests Nos. 1 and 2, one orderly pouch for each medical officer, one hospital corps pouch for the orderly, one surgeon's field case for each medical officer, one field desk, two litters and two lanterns. As these supplies have not all been received, owing to failure of contractors, improvisation had to be resorted to. The troops which have left for Cuba, however, have been equipped with the regulation supply, with the exception of the surgeons' field cases, which have not been received. Sufficient field cases (surgeons') have been obtained from well-equipped regiments in this camp and the departing troops have been supplied with at least one for each regiment. This method will be continued until a sufficient supply of field cases is received. They are scarcely necessary in war time and have been principally devised for duty with small commands in Indian warfare. In actual war major operations are not performed by regimental

surgeons but by the operating staff of division or brigade hospitals, and for minor operations the instrument case in the orderly pouch is sufficient. The sick of a regiment which can not be treated in quarters or with the means furnished to its medical department are sent to the division hospital.

Hospital service.—The hospital service for a command in the field is performed for the highest military unit by the division. A division hospital is established on the basis of 200 beds, the supplies for it or for its lesser units are provided for in the field supply table; tentage, transportation, ambulances and other equipments are obtained from the quartermaster department. The hospital is in charge of a medical officer detailed for the purpose, preferably a brigade surgeon or senior regimental officer of the command, who has for his staff an executive officer and a recording officer. The wards usually consist of twenty-four beds in four tents, each of which is under the charge of one or more medical officers, according to the gravity of the cases. The quartermasters and ordnance equipment will, under General Orders 76, War Department, be under charge of the two line officers detailed for the purpose.

The ambulance company.—The personnel of the division hospital, aside from the officers enumerated above, consists of as many hospital stewards as may be needed, detailed by the division commander to the division hospital from regimental hospital stewards. Privates of the hospital corps are either enlisted for that duty or transferred from regiments, the ratio of 2 per cent. of the command being the basis. These men are formed into a hospital company consisting of 196 men, under the command of a medical officer with three subordinate medical officers. The company is divided into three sections composed, as far as practicable, of men transferred from regiments forming the brigade. Each section is divided into three sub-sections composed of men transferred from respective regiments, in order that if a division hospital is in active service or changing station, or is divided into brigade or regimental hospitals, the men coming from each brigade or regiment will accompany their own organization. Each section will be further subdivided in conformity with its duties; one-half will be for duty in the division hospital, the other half will man the ambulance company, act as watchmen, accompany the regiment on the march, etc.

This establishment will be under the control of the chief surgeon of the division, who will receive his orders from the division commander in matters of military control and administration.

Medical service on the march.—When a command starts out on the march, each regiment will be supplied with three ambulances and its proportion of the hospital corps, from the ambulance service. The medical officers allowed by law will march with the regiment as mentioned above. The medical officers detailed by the division commander in division hospitals will march with the division hospital, if the hospital is to be moved; if not moved they will remain on duty with it. If any part of the command is permanently detached the division commander will order the medical officers and hospital stewards in division hospital to accompany the division hospital or its fractions, with its equipment.

Medical service in battle.—As soon as a regiment or command deploys for action, its medical department will wheel out of the way of the fighting force and be under the control of the senior officer present, who will assemble the detachments and ambulances in a place out of immediate reach of the enemy's bullets, preferably indicated by the military commander. Each regiment will be accompanied into action by its senior medical officer for duty, with his orderly and hospital steward, who will keep station with the commander. The division hospital will be located by the commanding General. As soon as practicable without exposing the hospital corps and ambulances to unnecessary crippling, the hospital corps, under command of the senior medical officer present, supplied with its litters, will commence the work of collection and assistance to the wounded, who will be carried to the collecting station and thence to the division hospital, or as a whole or in sections it will be advanced on the battlefield after an engagement.

The field hospital train.—The field hospital train is on a basis of one ambulance to every 400 men and one wagon to every 600 (one third the allowance of wagons is added when four mule wagons are used). This transportation is under the direct control of the line officer detailed for the purpose and will be parked in the vicinity of the division, brigade or regimental hospital as the case may be. The drivers of the ambulances will be privates of the hospital corps from the regiment to which they formerly belonged. The wagon drivers will be civilians.

When starting on the march the ambulances of each regiment will follow in the immediate rear of the regiment with

the detail of the hospital corps, and report to the senior surgeon of the regiment for instructions. The sick of the regiment requiring hospital treatment will be sent in the ambulance to the division hospital.

Dr. Frederick Holme Wiggin has recently been appointed, by the Commissioner of Public Charities of New York City, assistant visiting surgeon to Bellevue Hospital.

New Publications.—The *Medical and Surgical Monitor*, Vol. I, No. 1, June 15, 1898, issued at Indianapolis, and the *St. Louis Medical Gazette*, Vol. I, No. 1, June, 1898, are new monthly publications devoted to medicine and surgery.

Dry Labor.—Brodhead, in his service in the Sloane Maternity Hospital, has found that fully 15 per cent. of the women have labors which are strictly dry, "the accident" occurring nearly twice as often in multiparæ as in primiparæ. In the latter class the dry labor is usually more painful. He considers the dangers from this condition as dangerous to the child, *i. e.*, asphyxia and meningeal hemorrhage; dangers to the mother, *i. e.*, laceration of the soft parts, pressure necrosis, hemorrhage, sepsis, slower convalescence and possible rupture of the uterus. —*Med. Record*, May 14.

New Diagnostic Sign of Measles.—The value of Koplik's diagnostic sign (*vide JOURNAL*, vol. xxx, p. 1063) is confirmed by Libman in the *Medical Record* of June 11. His observations extend over fifty cases and in every case Koplik's sign was evident. He believes that "the mouths of children applying for admission to hospitals should regularly be examined for the measles spots." In addition to these fifty cases, the spots were observed in a number of dispensary patients, and in every case where the spots were evident, measles eruption was present or appeared within a few days.

Hemorrhoids.—Sims (*Maryland Med. Jour.*, May 7) advocates a new operative treatment applicable to the majority of cases of both internal and external hemorrhoids; also to other benign neoplasms of that region. With the patient in either the lithotomy or Sim's position, he introduces a speculum, divulges the sphincters as widely as possible by the instrument and with the thumbs stretches them until completely paralyzed. The piles now presenting themselves are everted as much as possible and the anal region irrigated with a 1 to 2000 bichlorid solution. On pulling out the tumors by forceps, the mucous membrane is cut through with a sharp scalpel around the base of the pile, and a silk ligature tied tightly in the groove made by the incision, including only the blood vessels and connective tissue. "The pile is then cut off close to the ligature, leaving only enough to hold it, and the cut edges of the mucosa are brought together over the stump with continued sutures of catgut." With external piles the same method may be used.

Large Doses of Carbolic Acid Given with Impunity.—Dr. Andrew H. Smith of New York says that in following out certain suggestions contained in an article in the *Lancet*, regarding the free administration of pure carbolic acid in scarlatina, he has been astounded at the enormous doses of carbolic acid that may be safely given to a person provided the acid used is pure. He also asserts that the occurrence of smoky urine, or "carbouluria," is no cause for alarm, as it does not imply any diseased condition of the kidney, and is not accompanied or followed by albuminuria. He has given patients the enormous daily dose of two and one-half drams of pure carbolic acid, diluted with water, and has kept this up for two or three weeks at a time without observing any deleterious effects from it. Of course, the urine of these patients was either smoky when voided, or became very dark after exposure to the air from oxidation of some of its constituents. These experiments, it need hardly be added, were not conducted for the purpose of satisfying an idle curiosity regarding what the human organism was capable of enduring, but with a view to a utilization of this, or some other similar antiseptic, in the internal treat-

ment of various infectious diseases.—*Philadelphia Medical Journal*, April 23.

New Light on Malaria.—R. Koch, who has just returned to Germany, devoted much of his two years in South Africa to a study of tropical malaria, which he considers resembles in many respects the Texas fever of animals and is, like that, conveyed by an intermediate agent, the tick in one and the mosquito in the other, but he has proved that the contagion is transmitted in the eggs of each, as well as by the insect itself. His most important achievement is his discovery of the exact temperature curve of tropical malarial fever. The temperature first rises and remains at this height for about half the length of the attack; then falls somewhat, returning abruptly to its former height, where it remains for the other half of the attack, which lasts about thirty-six hours in all, then rapidly falling to normal. The usual blind administration of quinin at regular intervals is absolutely useless. Quinin does not kill the plasmodium; it merely checks its development. We know now the exact moment when to administer it to produce the desired effect, which is the stage in the development of the plasmodium that precedes sporulation. *Quinin at the right moment cures tropical malaria even in its worst forms.* Koch confirmed this assumption in every case except two moribund. Draining swamps, planting eucalyptus, sanatoria, etc., are ineffectual prophylactic measures. The only effective measures are to keep mosquitoes away and out of residences (there is an island off the coast which is free from mosquitoes, and malaria is unknown there), and send scientific physicians to administer quinin at the proper moment. He adds that ten to fourteen days must elapse after infection before the plasmodia accumulate sufficiently to produce an attack. He considers the quotidian form the manifestation of two superposed tertian forms. He found four varieties of tropical malarial fever; two very rare; the third is the kind experienced in temperate countries, which occurs in 10 per cent. of the cases there, and the fourth, or very severe kind, in 90 per cent. He is convinced that the problem of artificial immunity will be solved in time, reasoning from the natural inherited immunity of the coast negroes and the acquired immunity of the negroes who, coming from the mosquitoless mountains down to the coast, pass through a severe attack and are immune afterward, like animals who have passed through an attack of Texas fever in youth when it is usually mild.—*Deut. Med. Woch.*, June 16.

Blood Examinations.—Heiman, in the *New York Medical Journal* of May 7, writes concerning "Current Methods of Blood Examinations." He points out that malarial organs must be distinguished from nucleated red cells, degenerated red corpuscles, plaques, precipitation of dye and fungi developed in the aqueous solution of methylene blue. The point of practical importance when staining is to be sure of finding the characteristic brown pigment of the malarial organism. He considers malarial disease endemic in New York and vicinity, especially on the river fronts. The specimen is stained with eosin-alcohol solution for five minutes, then washed well in water, dried with filter-paper, counterstained with concentrated aqueous methylene blue solution for two minutes, again washed in water, dried with filter-paper and mounted in balsam, when the specimen is ready for examination with an immersion-lens. He finds the plasmodia, as a rule, in the cells stained light bluish, their various forms depending on the stage of the disease. They have a characteristic small, brown, granular pigment in the sterile form and are clumped up in the center or periphery in the spore form.

Surgery of the Stomach.—In the *New York Medical Journal* of May 7, Keen of Philadelphia, gives a somewhat detailed review of the various operations now performed on the stomach. He considers that surgery of this organ has been rendered possible: 1. By the discovery of antiseptics. 2. By experiments

on animals. He says: "Had vivisection contributed nothing else to the progress of surgery, its services in the surgery of the stomach alone would be sufficient to justify it." He considers that gastrotomy has a somewhat restricted but still important field in gastric surgery, and that three indications exist for the operation of gastrotomy: 1. For the purpose of removing foreign bodies; 2, in cases of stricture of the esophagus, and 3, for exploration, each of which indication he considers in detail. He says: "That gastrotomy for malignant diseases does not save life is self-evident, but in preventing the patient from slowly starving to death, and in satisfying both hunger and thirst it is a most humane operation," and as it has relatively little danger, it can be commended even in desperate cases.

Sea Water for an Artificial Serum is warmly advocated by Quin-ton, who states that a dog injected with more than his own weight of sea water showed no signs of any abnormal phenomena. He has succeeded in keeping white corpuscles alive twenty-eight hours in sea water, three times the length of life of the same corpuscles in the ordinary artificial serum. Sea water must not be injected pure, or concentrated, but isotonic with the organic fluids. The experiments of others that tend to opposite conclusions are unreliable, as the isotonicity was not borne in mind and the osmotic pressure was rendered unequal, thus producing mechanical disturbances incorrectly ascribed to intoxication.—*Semaine Méd.*, May 25.

Movable Kidney.—Lichty reports twelve cases in the *Philadelphia Medical Journal* of May 14. Ten of these were of a decidedly nervous type; two of these had no nervous symptoms, one had sarcoma and the other disease of the kidneys causing displacement. He believes that it is associated in all cases where there is a decided loss of weight; especially when it occurs with the symptoms of movable kidneys, put the patient on a line of treatment which will restore his normal weight. He considers rest treatment very satisfactory for this, also exercises to strengthen the abdominal muscles. His conclusions are that movable kidneys may be easily overlooked, and unless due to some disease in the organ itself, it is consequent to faulty nutrition and always accompanied by some nervous symptoms; that the treatment of such must be directed toward the correction of the faulty nutrition, the use of a supporting bandage being advised, if this does not bring about disappearance of the symptoms. If the bandage brings about a disappearance of the symptoms and it later seems necessary to wear it continually, the patient should have a choice between this and a surgical operation. If the symptoms do not disappear after the normal weight is gained, or after a thorough trial of the bandage, the kidney should be fixed permanently by operation. If motility is due to disease in the organ itself, it should be removed early if allowable.

Liability of Charitable Hospitals for Negligence of Nurses.—A "private pay patient" was admitted to a charitable hospital to have a slight operation performed by her own private physician, who was also a visiting surgeon on the hospital staff. After the operation was successfully performed she was carried to her room, while still under the influence of the anesthetic, and placed in a bed from which a hot, uncovered water bag had not been removed by the nurse in attendance. To recover damages for the injuries sustained by her right leg thus being severely burned, she sued the hospital. But Judge Cohen of the supreme court of New York holds, *Ward vs. St. Vincent's Hospital*, March, 1898, that she had no cause of action against the institution, though he suggests that she doubtless had a good one against the nurse who was the wrongdoer. As he reads the cases, a public charitable hospital, which is doing no business for profit, but uses the money received from such pay patients as it has toward the support of the institution, which must still to a greater or less extent rely upon contributions of charitably disposed individuals, is liable only for negligence in the

original selection of its servants and, having fulfilled that duty, it is not liable for the subsequent act of such servants, however careless or negligent, unless previous knowledge of unfitness has been brought home to the corporation. Indeed, the judge thinks it may be doubted whether its liability extends beyond the selection of a competent head of the school of nurses connected with it. That the patient is a pay one, he does not consider changes the rule of liability, partly as it has been held in another class of cases that a charitable institution does not waive its exemptions because it charges some patients who are able to pay.

Skill and Care Required of Dentists.—Two distinct acts of malpractice were charged in the case of *McCracken vs. Smathers*, one in originally filling a tooth upon a live nerve, without proper packing, and the other in improperly and unnecessarily boring through the jaw bone after the party suing for damages had returned for treatment. Whether this malpractice, found by the jury, arose from the want of ordinary knowledge or skill, or the want of reasonable care on the part of the defendant, the supreme court of North Carolina says, March 15, 1898, is immaterial, as both are impliedly guaranteed by one offering his services to the public. The degree of care and skill required, it holds, is that possessed and exercised by the ordinary members of the profession. It need not be the highest skill and knowledge known to the profession, but it must be such as is ordinarily possessed by the average of the profession. It can not be measured simply by the profession in the neighborhood, as this standard of measurement would be entirely too variable and uncertain. "Neighborhood" might be construed into a very limited area. It might contain but few dentists, in sparsely settled sections perhaps only one or two. Both might be men of very inferior qualifications, and to say that they might set themselves up as the standard of a learned profession, and prove the standing of each by the ability of the other, continues the court, would be equally unjust to the profession and to its patients. The words "the neighborhood," as used in this connection, it further suggests, are essentially different from the phrases, "the same general neighborhood" or "the same general locality," which are found in some decisions from other States. But the supreme court expresses itself as satisfied with the instructions given the jury to the effect that the defendant would not be liable if he had exercised ordinary skill and care, and that, if he failed in either of these particulars, he would be responsible for the damages resulting from his own acts alone. Judgment for plaintiff affirmed.

Hypertrophic Pulmonary Osteo-Arthropathy.—In the *New York Medical Journal* of May 14 Hasbrouck reports a case of the above, previously there being but five cases in this country on record. The patient was a male, colored, aged 55 years, a laboring man, and in April, 1896, a small swelling appeared just beneath the right lower jaw, grew slowly, then later enlarged rapidly and in March, 1897, involved the entire tongue and all the glands of the right side of the neck. Respiration, deglutition and articulation were exceedingly difficult and the tongue could not be protruded beyond the lips, as the tumor mass pressed it well over to the left side of the mouth. Later the enlargement affected the hands, feet and ankles until it was impossible for him to close his fists. The knee- and elbow-joints did not take part in this enlargement, but the distal extremities of the ulna and radius of both arms did, as was shown by skiagraph, also the carpal bones. From the skiagraph the enlargement seemed to be purely periosteal in formation, but unfortunately this could not be verified by postmortem. In reviewing the cases he finds that in all but one case there has been some chest lesion, and in this one exception he believes a pulmonary disease was associated. The patient died from general sarcomatous infiltration, and the writer concludes that the disease is secondary to sarcoma, that

in accordance with evidence from previous cases, it is due to some obstructive pulmonary lesion, this being substantiated by postmortem findings, where a hardened mass firmly binding the aorta, the esophagus and trachea into one solid body, in addition to the sarcoma of the mouth and the several sarcomatous areas in the right lung. He also believes that had the primary condition been less malignant, giving the secondary more time, a much more typical condition of the feet and legs would have developed, as they were just beginning to share in the enlargement a few weeks before death.

First Qualified Woman Physician in Europe.—The first qualified woman physician in Europe, as far as is known, was a young Athenian woman named Agnodice. In the year 300 B.C., she disguised herself as a man and began to attend the medical schools at Athens, which it was against the law for a woman to do. She afterward practiced among the women of Athens with extraordinary success. Her secret becoming known, she was prosecuted for studying and practicing medicine illegally. The Athenian women, however, raised so furious an agitation in consequence that the case was dropped and the law repealed. Coming to later times, we find several women who obtained the degree of doctor of medicine and practiced in Europe before 1492, especially in the Moorish universities of Spain. Trotula of Rugiero, in the eleventh century, had a European reputation and practiced in Salerno. At the beginning of the fourteenth century Dorothea Bocchi not only received the degree of doctor but was professor of medicine in the University of Bologna. Since then two other women have been professors of medical subjects in the same university, Anna Mangolini (anatomy) and Dr. Maria delle Donne (obstetric medicine), the latter being appointed in 1799. In the year 1311 an edict was issued in France forbidding surgeons and female surgeons from practicing until they had passed a satisfactory examination before the proper authorities. These female surgeons are again referred to in an edict in 1352.

Allows no Insurance for Septic Poisoning.—In an action brought to recover on a policy of accident and life insurance the evidence tended to show that the insured, while suffering from some serious derangement of his system, which manifested itself, among other ways, by severe toothache, had two of his teeth extracted by a dentist; that there was a diseased condition of the membrane surrounding some of the teeth, and a general foul condition of the mouth; that the teeth were extracted in the usual way, but it caused a rupture of the upper maxillary artery, or a branch of it, from which a violent hemorrhage ensued, and to stop that the dentist plugged the cavities with cotton; that thereafter blood poisoning ensued from the absorption into the system of some chemic poison supposed to have been caused by the propagation of disease germs in the cotton, the seat of the affection being where the teeth were extracted, which blood poisoning progressed to a fatal determination. Under these circumstances, the supreme court of Wisconsin reversed a judgment rendered against the insurance company. It holds, March 22, 1898, *Kasten vs. Interstate Casualty Company*, that, under a policy insuring a person against bodily injury sustained by external, violent and accidental means, with a provision for payment to a beneficiary or beneficiaries in case of death from such injuries within ninety days therefrom, independently of all other causes, and with a condition that the liability of the insurer shall not extend to injuries, fatal or otherwise, resulting wholly or in part from poison or anything accidentally or otherwise taken, administered, absorbed or inhaled, a death under such circumstances as above stated is within the condition set forth and creates no liability against the insurance company.

Fracture of the Lower Extremities.—Warbasse (*Annals of Surgery* for May) reports observations on the treatment of fractures of the lower extremity during two years, in the Methodist

Episcopal Hospital of Brooklyn. This fractures include 111 of the femur, 34 of the patella, 19 of the bones of the foot and 286 of the bones of the leg. Of the 111 cases of fracture of the femur, 81 were discharged cured, 7 improving and 2 with soft unions; and of 70 cases of complete fracture of the shaft or neck in which the exact measurements were kept, there was no shortening in 36 cases, less than one-fourth of an inch in 20 cases, from one-fourth to one-half inch in 8 cases, from one-half to three-fourths inch in three cases, from three-fourths to one inch in two cases and two inch shortening in one case. Both femora were broken in three cases and there were two cases of separation of the lower epiphysis. In the majority of cases the treatment applied was the traction apparatus of Buck. In 20 of the cases of fracture of the patella in which the joint was opened by incision over the patella, solid bony union was secured in all, the bone being united by silver wire sutures in twelve cases, by silkworm gut in five, by kangaroo tendon in one and by chromicized gut in one case. In three cases where the patella was encircled by a subcutaneous suture, good fibrous union was secured. In 27 operations in which the knee joint was opened and the bone fragment sutured, there was no septic joint disturbance. Primary healing occurred in all cases and it was demonstrated in all of the recent transverse fractures that bony approximation would have been absolutely impossible without operation because of the intervention of blood clot and torn periosteum. During the latter part of the decade drainage was used less than in the early part and the cases did equally well without it. Lately a method of uniting the bones by chromicized sutures passed through the bone, suturing over these the periosteum with interrupted chromicized gut sutures, then closing the joint capsule by a continuous suture of fine gut, suturing the subcutaneous fascia in the same manner and finally closing the skin with a suture of silk, gave great satisfaction. Of the 286 cases of fracture of the tibia and fibula, 136 were of the shafts of both bones of unspecified location, 28 of the shaft of the tibia and 21 of the shaft of the fibula of unspecified location, 8 of the upper thirds of both bones, 15 of the middle and 28 of the lower thirds, 4 of the upper third of the tibia, one of the middle and 13 of the lower third, 3 of the upper third of the fibula, one of the middle and 30 of the lower third. Of these, 180 were simple fractures, 90 compound fractures, of which number 56 were compound comminuted and 5 simple comminuted. In the 19 cases of fracture of the bones of the foot, 10 were fractures of the tarsal, 5 of the metatarsal and 4 of the phalanges.

Colleges.

The Medical Department of the University of Vermont graduated a class of sixty-nine at the annual commencement, June 30.—The graduating class of Bowdoin Medical School, Brunswick, Me., at the annual commencement, June 22, numbered thirty-three.

Hospitals.

The new Finley Hospital was opened at Dubuque, Iowa, June 21.—Henry M. Flagler has offered to the Red Cross all the necessary land and \$5000 with which to build a hospital for the wounded just north of the Royal Palm Hotel, Miami, Fla. He also offers the use of a new pier, upon which the hospital may be built, or it may be placed on adjacent land.

Philadelphia.

SPECIALIST IN TROUBLE.—Miss Ella Moore, who has an office at 1228 Brown Street, recently treated a patient for a tumor, and on the patient's death the deputy coroner held a postmortem and found that cancer was the primary cause. The woman, who claimed to be a specialist, was placed under arrest, and at the trial testified that she was in the employ of a firm on Walnut Street who prepared a salve which was said to be a specific for tumors. It is further reported that the specialist who gave the treatment subsequently called in a physician, obtained

money and then disappeared. The woman died in terrible agony. As the specialist's sign read "Doctor Ella Moore, Specialist," her case will be thoroughly investigated by the Philadelphia County Medical Society.

UNIVERSITY OF PENNSYLVANIA ADVANCES.—Physiologic chemistry some day will be one of the most important branches in the curriculum of all medical colleges. Yale College deserves great credit for having already established this department and inviting the younger men to take hold of the work with great assiduity. Correlated with this branch of medicine stands physiology and therapeutics, and the University of Pennsylvania has not been slow in finding this out, and hereafter students who graduate from that university will have some idea of the physiology of digestion, of electric appliances and of physiologic chemistry, for this department will be devoted to that work. Since extensive college buildings for dental students have been erected, the room formerly occupied by them as an operating-room or clinic will be partly devoted toward instructing students in experimental physiology. In the new department Dr. H. C. Wood will have his private laboratory for this study, and more elaborate experiments can be made than has formerly been the case. Dr. John P. Arnold, a graduate of the university, class of '93, will have full charge of the laboratory for experimental physiology. When these laboratories are completed they will be an improvement of which any college may feel proud.

ETIOLOGY OF THERMIC FEVER.—The past week has been one marked by most depressing weather, there being hardly wind enough to turn a weather-vane. Indeed, the heat has never ceased and the humidity at times has almost gone to the saturation point. June 25 was the hottest day up to that period, registering 94 degrees at 4 p.m., with the humidity at 98 degrees, and ending with twelve prostrations. Four days later the morning started off sultry and really seemed much hotter than the thermometer indicated, 88 degrees, but the humidity had risen to 90 degrees, resulting in nine prostrations for the day. The mercury rose higher on July 1, registering 97 degrees, the humidity being 70, and causing sixteen prostrations. July 3, according to the weather report, was the hottest day for that period in twenty-eight years, the mercury rising to the century mark, and that on top of an elevated building, the Philadelphia postoffice. The humidity was 70 degrees. So far there have been reported seventeen prostrations, four of which resulted fatally. The heat, the humidity and the velocity of the wind seem to be most important factors.

MORTALITY STATISTICS.—For the week ending July 2 there have been 555 deaths. Of these, 284 were children under five years of age. The number of deaths during the week is an increase of 168 over last week and 64 over the corresponding period of last year. The principal causes of deaths were: Cholera infantum, 114 deaths; marasmus, 28; heart disease, 27; consumption, 47; inflammation of lungs, 27; inflammation of stomach and bowels, 26; nephritis, 19; old age, 16; convulsions, 16; sunstroke, 4; uremia, 5; cancer, 12. The infectious diseases this week were: Diphtheria, 56 cases; scarlet fever, 26 cases; typhoid fever, 10 deaths in 51 cases. Last week the record was: Diphtheria, 9 deaths in 49 cases; scarlet fever, 2 deaths in 40 cases; typhoid fever, 7 deaths in 79 cases.

APPOINTMENT OF HEALTH OFFICER.—Some time ago the Health Officer of Philadelphia, Dr. Benjamin Lee, addressed a letter of inquiry to city solicitor John L. Kinsey, in which he desired the information as to whether or not the appointments made by him should also be ratified by council. Solicitor Kinsey replied that since the Board of Health had been a part of the Department of Public Safety of the Municipal Bureau, the appointments connected with the Board of Health would therefore come under the provisions of the act made applicable to the other various departments, and therefore, appointments

made by the Health Officer would also have to be confirmed by select council.

INJUNCTION.—Some time ago Messrs. Edwin Chesterman and George M. Streeter filed suit against Isaac B. Seeley restraining him from using that firm's name in business. In the court of common pleas, Judge Pennypacker recently handed down the following decree: "That the said I. B. Seeley is hereby enjoined from the use of the words 'Only Seeley' established since 1859, and impersonators,' and that all postal matter relating to the truss business addressed to Seeley's Truss Establishment with any address other than 1027 Walnut Street, or I. B. Seeley & Co., and also all letters or orders from customers of the old firm of I. B. Seeley & Co. are to be delivered to the plaintiff."

ROBERT BOYD, M.D., has recently been appointed assistant surgeon in the United States Army. Dr. Boyd will doubtless make a valuable addition to the corps of physicians already there, on account of his knowledge of the diseases of Cuba, he having at one time resided there. Dr. Boyd will report for duty at Tampa, Fla.

Louisville.

DEGREES.—Two Louisville physicians have been honored in the past month by having been the recipients of the degree of LL.D. Dr. Jos. B. Marvin had the degree conferred by Georgetown College, this State, and Dr. Joseph M. Mathews, President-elect of the A.M.A., by the Waynesburg College of Pennsylvania.

DR. LOUIS FRANK has removed his office from corner of Second and Chestnut, where he has been associated with Dr. T. H. Stucky, to 231 W. Chestnut Street.

HOSPITAL.—The annual commencement of the Louisville Training School for Nurses was held in the lecture-room of the Louisville Medical College on the evening of June 15, there being seven graduates.

WASH FITHIAN, M.D., one of the most prominent physicians of Paris, Ky., was stricken with apoplexy in his office June 28. His condition is not considered very grave.

ALUMNI.—The annual meeting of the Alumni Associations of the Louisville College of Dentistry and of the Hospital College of Medicine were held in the college buildings on June 28 and 29. Interesting clinics were held, papers read and a banquet held at Fountain Ferry Park.

COMMENCEMENT.—The annual commencement exercises of the Kentucky School of Medicine were held in Macauley's Theater on June 29, there being 140 graduates. Degrees were conferred by Dr. R. Lin Cave, president of the Kentucky University and Mr. James P. Helm, president of the Board of Regents of the Kentucky School of Medicine. An address was made by Dr. James S. Sweeney, Sr., president of the Board of Trustees of the Kentucky University and by Dr. George R. White, valedictorian of the class. Dr. Geo. T. Harris and Dr. Sidney J. Meyers received the first honors for the fourth and third years respectively.

HOSPITAL COLLEGE OF MEDICINE.—The annual commencement exercises of the Hospital College of Medicine and the Louisville College of Dentistry were held at Macauley's Theater on June 30. There were 130 graduates. The annual address was made by Dr. C. A. L. Reed of Cincinnati, there being no address from a member of the class, this being the custom at this school for some years. A portrait of Dr. J. A. Larrabee, who was president of the faculty, was placed in the center of the stage draped in mourning. Lewis S. McMurtry has been elected president of the faculty, vice Dr. Larrabee deceased, and has had added to his chair of gynecology and abdominal surgery that of obstetrics taught by Dr. Larrabee. This is a well-merited honor as Dr. McMurtry has a wide reputation as a skillful surgeon. Thos. H. Stucky was elected vice-president and H. H. Grant treasurer. The chair of pediatrics was added to the chair of chemistry now held by P. F. Barbour.

HEALTH OFFICER.—The monthly report of Health Officer Allen contains some interesting statements: Notices served, 459; nuisances abated 1897; sheep and cattle condemned and killed 21; scarlet fever placarded 7, and diphtheria 1; specimens of milk examined 52, number found below the standard 5; births

reported 79, marriages reported 10. A large number of physicians are receiving the badges issued by ordinance giving them right of way over streets when making professional calls; recommendation is made that water-plugs be placed at certain places in the city, that filthy gutters may be flushed and cleaned; pavers to be used by embalmers to show they are legally licensed are ready for distribution; there were 236 deaths during the month of June against 300 last June; of these 117 were males and 119 females; cholera infantum caused 17 of the deaths and consumption 18, cerebral meningitis 12, and organic heart disease 10.

DUNCAN EVE, M.D., Nashville, chairman of the Committee of Arrangements of the Mississippi Valley Medical Association was in the city one day last week to confer with the secretary and a number of the local committee for the Louisville meeting relative to the meeting of the Association in Nashville in October next.

Societies.

The following recent meetings are noted:

Alabama.—Calhoun County Medical Society, Anniston, July 5.

Illinois.—Chicago Medical Society, June 29; Tri-County Medical Society, Paxton, July 6.

Indiana.—Grant County Medical Society, Marion, June 16; Lawrence County Medical Society, Mitchell, June 23.

Iowa.—Central Iowa Medical Association, Webster City, June 21; Des Moines Valley Medical Society, Ottumwa, June 23; Dubuque Medical Society, June 23; Sioux Valley Medical Association, Sheldon, June 23; Eastern Iowa District Medical Association, Burlington, June 30; Austin Flint Medical Association, Iowa Falls, July 12 and 13; Scott County Medical Association, Davenport, June 30.

Maryland.—Tri-State Medical Society, Cumberland, June 23.

New Jersey.—State Medical Society, Asbury Park, June 29 and 30.

New York.—Broome County Medical Society, Binghamton, July 5; Erie County Medical Society, Buffalo, June 14; Syracuse Academy of Medicine, June 21.

Ohio.—Columbus Academy of Medicine, June 20; Lucas County Medical Society, Toledo, June 17; Tri-County Medical Society, Ashtabula, July 5.

Pennsylvania.—Northumberland County Medical Association, Milton, June 30; Tioga County Medical Society, Lawrenceville.

South Dakota.—South Dakota Medical Society, Sioux Falls, June 15 and 16.

Texas.—North Texas Medical Association, Fort Worth, June 21 and 22.

West Virginia.—Mason County Medical Society, Point Pleasant, June 30.

Wisconsin.—Central Wisconsin Medical Society, Janesville, June 23; Northwestern Wisconsin Medical Association, Stevens Point, July 12.

Yellow Fever.—As we go to press with the last form, we read in the press dispatches of the outbreak of yellow fever among the troops. This need occasion no alarm, as no more efficient hygienic corps exists than may be found in the Army. The disinfection of all baggage of all persons entering our lines from Santiago, whether refugees or prisoners, may have to be carried out.

THE PUBLIC SERVICE.

Movements of Medical Officers.—To report to General Brooke at Chickamauga Park, Georgia, Acting Assistant Surgeon Humphrey Bate, Jr., from Castalian Springs, Tennessee. To the 4th Corps, General Coppinger, at Tampa, Florida: Acting Assistant Surgeons E. H. Morton and Samuel W. Kelley. To the General Hospital at Key West, Florida: Acting Assistant Surgeon T. A. Clayton. To the General Hospital at Fort Monroe, Virginia: Acting Assistant Surgeons Baer Street from Sheridan's Point and Otway W. Rush from Madisonville, New York. To the Hospital Ship *Relief*: Major A. E. Bradley, Brigade Surgeon. To the 5th Army Corps, General Shafter, at Santiago, Cuba: Acting Assistant Surgeons Stanley Warren, Charles C. Marbury, Jas. VeV. Mackall, A. A. Snyder, Jesse Ramsburgh, Henry L. Brown, Jas. T. Corwin, John R. Hicks, Rufus D. Boss, John D. Thomas, Edward J. Meyer,

Charles Brewer, Joseph L. Sanford, John W. Wright, H. C. Cline, Russel W. Chidsey, J. H. Feuss, J. S. White and Ezequiel de la Callé.

Resigned: Major Arthur L. Osborn, Surgeon 6th Ohio Volunteer Infantry.

Nominations, most of which were confirmed on the closing day of the session: To be chief surgeon with the rank of Lieutenant-Colonel, P. F. Harvey, Major and Surgeon U. S. Army. To be chief surgeons of division with the rank of Major: Nelson H. Henry, Assistant Surgeon-General of New York; Victor C. Vaughan, Surgeon 33rd Michigan Volunteers; Charles M. Robertson, Surgeon 50th Iowa Volunteers. To be chief surgeons of brigade with the rank of Major, Royce Day Fry of Ohio; Elmer E. Heg of Washington; Charles R. Parke, Surgeon 13th Pennsylvania Volunteers; Jabez N. Jackson, 3rd Missouri Volunteers; Wallace Heff of Ohio; Geo. F. Shiels of California; Wm. S. Bryant, Assistant Surgeon 1st Massachusetts Heavy Artillery; Wm. F. Deniedeman, Assistant Surgeon 22nd Kansas Volunteers; Francis C. Ford of Texas and Lawrence C. Carr of Ohio.

CHANGE OF ADDRESS.

Bozinch, M. F., from 291 N. Carpenter St. to 162 W. Chicago Ave., Chicago, Ill.

Bulete, W. W., from 149 Santa Fe St. to Central Block, Pueblo, Colo.

Childs, C. F., from Decatur to Irondale, Ill.

Furay, C. E., from 2409 N St., South Omaha, to 2237 Seward St., Omaha, Neb.

Franklin, G. W., from Jefferson, Iowa, to Good Samaritan Hospital, Portland, Ore.

Flsk, F. F., from Waterloo, Iowa, to Cedar City, Utah.

Hoff, F., from 510 Walnut St. to 200 Grand Ave East, Des Moines, Iowa.

Hawes, E. E., from 818 Broadway to 164 Washington Ave., Boston, Mass.

Heath, C. L., from Treveille, Tenn., to Lindsay, Ky.

Kerr, A. W., from Keene, Texas, to Woodburn, Iowa.

Lambert, F. E., from Iowa City to Alburnett, Iowa.

Murphy, J. A., from Cincinnati, Ohio, to Wequetonsing, Mich.

McNicholl, T. A., from Sea Cliff, L. I., to 140 E. 39th St., New York, N. Y.

Monroe, J., from Markesan, Wis., to Blackfoot, Idaho.

Morton, G., from Rialto Bldg to 14 E. 11th St., Kansas City, Mo.

Moe, A. J., from 353 Western Ave., Chicago, Ill., to La Crosse, Wis.

Nichols, C. B., from Denver, Colo., to Fort Wingate, N. M.

Perry, J. G., from New York, N. Y., to Ridgefield, Conn.

Purcell, E. C., from Denver to Elyria, Colo.

Roberts, N. G., from Denver to Littleton, Colo.

Smith, C. B., from Decatur to Lorington, Ill.

Smalt, A. E., from Stillwater to Willow River, Minn.

Whittaker, J. T., from Cincinnati, Ohio, to Lakewood, N. Y.

Wood, L. H., from 1005 Boulevard to 2405 Boulevard F., Denver, Colo.

Whitfield, B. W., from Galloway to Demopolis, Ala.

York, F. A., from Galveston, Texas, to Denver, Colo.

No. 4.

ANNUAL ORATION.

SURGERY OF THE LUNG.

The Oration in Surgery Delivered at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Col., June 7-10, 1898.

BY J. B. MURPHY, M.D.

CHICAGO, ILL.

Mr. President and Members of the American Medical Association:—Permit me to express my appreciation of the great honor conferred on me when elected to deliver the Annual Address on Surgery to this distinguished body of scientists. Custom has ordained that the address in the specialties of medicine at our annual convocation should be confined to a review of the advancements of the science and art of this branch in general in the preceding year. I take the liberty of deviating a little from this precedent to review the efforts and achievements made in a special and, until the last two decades, neglected field of surgery. I believe I am justified in this digression, as at the last, our semi-centennial convention, my predecessor enumerated and so emphasized the achievements of surgery for the last half century that I fear the consideration of a year's progress would be of small interest.

I have therefore chosen for my subject today the surgery of the lung. An analysis of the accomplishments in this special line of work is of great interest, the advancements having been made by individual and unsupported efforts. The profession at large has never entered into this field with the enthusiasm, persistency and energy with which it has invaded other fields, as the peritoneum, the genito-urinary, the osseous and nervous systems. Indeed, if we were to take from the list of original investigators and operators in this field thirty names, it would be practically a blank; the work has been of a desultory character. The surgery of the lung has had its epochs of advancement. In no field of medicine has the intermittence in surgical effort been so conspicuous as in that of the lung. We find that Hippocrates, in the fourth century, B. C., recognized that pneumonic abscesses opened into the bronchus and slowly recovered in that way. He repeatedly opened them through the chest wall and resected the rib to obtain a better field. He advised thoracotomy and pneumotomy as the proper treatment for this class of cases¹. These operations were then lost sight of and did not come to light again until 1584, when Schenk² recommended them. Oblivion was its fate again until Willis in 1664 drew attention to it. Bligney in 1670 reported a case of phthisis which was cured by accidental puncture of the chest with a sword; the opening allowed the pus to escape from the lung. Purmann in 1692 advised incision of the chest wall

in hemorrhage, empyema and pulmonary cavities, and for removal of all kinds of effusions. Baglini in 1696 opened the chest. Baglivus in 1710 treated wounds of the lung by free incision of pleura and advised the same treatment for phthisical cavities. Berry of Dublin, in 1726, suggested the drainage of pulmonary cavities, and cited cases of recovery following pulmonary incision. Sharpe in 1769 dwelt on the difficulties of separating pleuritic adhesions and advised cutting into the cavity with the lance and inserting tubular drainage.³ Pouteau and David in 1783 advised incision to pleura and trocar to depth of pus.⁴ Faye in 1797 operated for abscess of the lung which was adherent, and advised puncture, irrigation and tampon; for such cases Jaymes and Richerand in 1813 advised incision.⁵ H. Callisen in 1815 advised puncture and exploration of the chest by paracentesis, and if pus were detected, incision of the pleura; then digital palpation for fluctuation in the lung with immediate incision.⁶ Zang in 1818 reported fifteen incisions of the chest wall, seven for empyema and eight for abscess. Nasse in 1824 incised a pulmonary cavity.⁷ Krimer in 1830 wished to perform this operation, but the medical consultant would not consent. Brichatan in 1830 opened a cavity with a caustic paste and also one with the scalpel, in which he cut into the lung a distance of eight lines and then dilated with forceps. The latter patient lived nine months. Postmortem showed the cavity obliterated.⁸ To the above list of investigators may be added the names of Brichet, 1831; McLeod, 1836; Clausen, 1839; Hastings, Herf and Collins, 1844. Then came a long period of quiescence until we find the subject again receiving attention as a modern advancement in 1873 by Mosler and Pepper.⁹ Neisler, 1873, drained a tubercular cavity of the lung. The work of F. Mosler is conspicuous as he, though a medical man, advocated in repeated theses surgical interference in diseases of the chest. His efforts were ably supported by Koch and Bull, and the experiments of Gluck, Block, Hans Schmid, D. Biondi, and by the cases of Rugge, Christian Fenger, E. W. Andrews, Kroenlein, Omboni, Roswell Park, B. Pitts, Fabricant and others.

It would be impracticable for me to enumerate here the names of men who have labored so zealously in the interest of surgery of the lung, as they will be given due credit under the special headings to which their investigations contributed. Let us consider, first, the anatomy; second, the physiology; third, the experimental research, and fourth, the course and results in clinical cases. The last two we will take up under the headings of separate opera-

tions or pathologic conditions, while the first two, the anatomy and physiology, will be treated of here.

Anatomy.—The lungs are almost entirely situated within the bony cavity of the chest, the exception being the small projection of the apices above the level of the first rib. A straight line drawn, however, from the upper surface of the first rib behind to the upper surface of the clavicle in front, would pass above the apices. A straight line drawn in any position from the margin of the ribs and costal cartilages or sternum across the chest cavity below would not touch the lung. The chest has two diaphragms, the first closing a small kidney-shaped orifice, made up by the combined arches of the first ribs, the sternum in front and the spine behind. The large vessels of the neck, the trachea, esophagus and nerves pass through this orifice. This diaphragm rises and falls with each respiratory act, from one-half to one and

The space embraced within the chest is filled in behind, first, by the anterior curvature of the heads and necks of the ribs and the bodies of the dorsal vertebrae; the spinal column extending far forward helps to make up the mediastinal septum, which divides the chest into two irregular flattened cones. The distance from the sternum to the spine is about two-thirds of the depth of the thickest portion of the cone, which is from the most prominent posterior part of the arc of the rib directly forward (as shown in Figs. 5 and 6 from Fowler and Godlee).

The hilum of the lung resting anterior to the spine is therefore about midway between the anterior and posterior margins of the chest cavity as outlined by the ribs. The anomalies of the ribs and the shape of the chest change the respective relations between portions of the lung and chest wall, and must be consid-

Fig. 1.—Normal healthy subject.

one-half inches in extent, depending upon the respiratory effort and the condition of the respiratory organs, moving most in health and least, if at all, in apical disease. The chest, from its upper diaphragm, in its normal shape represents a continuous conical expansion to the lower margin of the ribs. (See Fig. 1.) The dress in females converts it into a balloon shape; the same is true of emphysema; the most expanded portion of the chest, under these circumstances, is about the lower margin of the fifth rib; it then contracts to the costal margin of the twelfth rib. (See Fig. 2.) For many years it was the prevalent opinion that the lung filled the greater portion of the chest. The modern anatomist has demonstrated on frozen specimens that only a small portion of this cavity is occupied by the lung. The radiographs which I have had made show that the position of the diaphragm in the frozen specimen and cadaver is misleading. (See Figs. 3 and 4.)

Fig. 2.—Deformed by tight lacing.

ered in the surgery of the individual case. When a seventh cervical rib is present it extends far above the level of the apex of the lung and may compress it, but it is not so likely to interfere with the lung as with the roots of the brachial plexus. An additional dorsal rib is usually accompanied by an elongation of the pleural cavity at that point, but the lung does not fill the pleura to its margin. A bifurcation of the ribs anteriorly has no particular influence upon the chest. The seventh is usually the last true rib; the eighth, however, is occasionally joined to the sternum. The width of the intercostal spaces is of importance; it is greatest in the second and third and tenth and eleventh, and is widest just at the tip of the bony end; it can be increased to its greatest degree when the spine is erect, but is not necessarily increased on inspiration. A division of the pectoral and intercostal muscles allows of a great increase in the separation of the ribs; this is most marked in the young.

The space in children attained in this manner usually suffices for operation without costal resection.

The sternum is not perpendicular; it deviates from this about 25 degrees. Its angle ranges in the respiratory act between the 160th and the 170th degrees. (Fowler and Godlee.)

The diaphragm forms the lower elastic, irregularly convex boundary of the chest. It is a very large-sized muscle with firm attachments to the entire circumference of the lower margin of the chest. It is in constant movement in health, and is the most powerful individual respiratory muscle. It is the piston of respiration; the chest wall is the cylinder. See

abdominal pressure. The arch and length of the diaphragm are changed by the shape of the chest; it is shorter and higher arched in the hollow-shaped chest of females and emphysemata. In the balloon-shaped chest the diaphragm has the least action; this shape is considered a predisposing cause to phthisis. The degree of the vaulting of the diaphragm into the chest in life has been overestimated by anatomists from the examination made by them on the cadaver and frozen specimens; a study of my radiographs, a few of which

Fig. 3.—Sagittal section (right) after Rüdinger. Cl, clavicle; Sc, scapula; D, diaphragm; U.L., upper lobe of lung; M.L., middle lobe of lung; L.L., lower lobe of lung. The pleura is indicated by heavy lines.

Figs. 7 and 8. Its vaulting within the chest cavity is of the utmost import to the physician and surgeon. It is divided into two almost equal parts; the central and front part, corresponding to the position of the heart, is the highest and is practically stationary. It is on a level with the fourth interspace on the right side, with the sixth rib in the axillary line and with the eighth rib in the scapular line and the body of the ninth dorsal vertebra. On the left side at the points mentioned it is five-eighths of an inch lower. In health it varies from the third to the sixth interspaces in its vaulting. (See Figs. 7 and 8.) The origin of the central (spinal) portion is fixed, and its vaulting is changed by the contraction and relaxation of the diaphragmatic muscle assisted by the intra-

Fig. 4.—Sagittal section (left) after Rüdinger. Cl, clavicle; Sc, scapula; D, diaphragm; U.L., upper lobe of lung; L.L., lower lobe of lung. The pleura is indicated by heavy lines.

are here reproduced, will show that the diaphragm in forced expiration elevates to a level with the lower margin of the fifth rib in the extreme and usually only to the sixth rib. In forced inspiration it is an inch to an inch and a half lower.

It will be seen in radiograph No. 1, which was taken in full inspiration, held for seventy seconds during the entire exposure, that the diaphragm on the right side comes to a level with the middle of the seventh rib at its cartilaginous junction; on the left side that it is about three-eighths of an inch lower and passes to the margin of the ribs with a lesser vault.

Radiograph No. 2 shows that in complete expiration, held for forty seconds during the entire exposure in the same healthy individual, the highest

RADIOGRAPH No. 1.

portion of the diaphragm came to the upper margin of the sixth rib on the right side and was about one-fourth inch lower on the left. This shows the degree of movement of the diaphragm in the respiratory act.

Radiograph No. 3, from a male adult, exposure forty-five seconds, shows in complete retained inspiration that the diaphragm on the right side comes to the middle of the sixth interspace, and on the left side it extends about three-eighths inch higher. Radiograph No. 4, from same person as No. 3, shows the position of the diaphragm during complete exposure of forty-five seconds in extreme expiration; the diaphragm on the right side comes to a level with the lower margin of the fifth rib, and on the left side it extends about one-third of an inch lower.

Radiograph No. 5, Miss K., emaciated female, shows the diaphragm on the right side as taken during normal respiratory movements, face down; it extends to the lower margin of the fifth rib; the outline is not discernible on the left side. Radiograph No. 6, back

the rib cartilages about one-half inch from the sternum. At the sixth space it subdivides into the superior epigastric and musculo-phrenic; it gives off small intercostal branches in its course. An anomaly of this artery, an early subdivision at the second or third space, may occur and a large branch extend outward and downward in the direction of the nipple. This branch would be interfered with in most operations through the anterior wall of the chest. In operations on and accidents to the anterior chest wall the location of the internal mammary artery should be distinctly borne in mind, as fatal hemorrhage has occurred from incisions, or injuries to this artery. The intercostal veins empty into the azygos and superior intercostal veins. The azygos veins are large and flat and have scarcely a plus pressure. In separating the adhesions of a diseased apex on the mediastinal side the azygos must be given great consideration, as it is easily torn and has a double danger, hemorrhage and air embolus; the azygos completely collapsed in the

The pleura is indicated by heavy line.

down; Miss K., the same individual as radiograph No. 5, shows the diaphragm on the right side as taken during normal respiration; it extends to a level with the upper margin of the fifth rib in front and on a level with the middle of the tenth rib behind; the diaphragm on the left side is one-fourth inch lower. Radiograph No. 7, Miss K., showed the same result. The results in an additional number of radiographs not here reproduced have been practically the same.

The chest wall is supplied with blood by the intercostal arteries; the first branch is given off from the subclavian and the others from the posterior surface of the aorta. They are close to the pleura behind and separated from it with the accompanying veins in front by the intercostal muscles. In addition the chest wall receives a blood supply from the internal mammary artery, which runs down behind the sterno-clavicular articulation, along the posterior surface of

dog with each inspiratory act. (See Fig. 9, azygos vein and internal mammary artery.)

Lymphatics.—The lymphatics of the chest wall connect with the intercostal glands situated at the costo-vertebral junction. The efferent vessels from these glands empty into the thoracic duct, their lower branches into the receptaculum chyli. In front they run forward with the internal mammary artery and vein, where they have additional glands (sternal). The substernal glands also receive lymphatics from the anterior abdominal wall, diaphragm and liver. This anatomic feature explains the secondary mediastinal infections and tumors which occur from diseased foci at and below the diaphragm.

The mediastinum is best studied with the classification of Quain: the superior mediastinum, is that above a line drawn on a level with the upper border of the pericardium from the lower portion of the fourth dorsal vertebra behind to the junction of the

manubrium with the body of the sternum in front. It contains the trachea, esophagus, thoracic duct, the arch of the aorta, the innominate, left common carotid and subclavian arteries, innominate veins and the upper part of the superior vena cava, the phrenic and pneumostic nerves, the left recurrent and cardiac nerves, the cardiac lymphatics and the remains of the thymus gland. The anterior mediastinum is the narrow upper half; the two pleuræ come in contact in this position, and occasionally have a communicating foramen. This opening is more common in the dog and is very detrimental to experiments. It is less frequently found in the guinea pig and rabbit. In monunguals (single hoofed animals) it is always present. When a foramen does not exist in the dog the mediastinum not infrequently ruptures at this point, when one side of the chest is opened, and allows both lungs to collapse. The septum is thinnest behind the second portion of the sternum, and the pleuræ diverge above and below from that point. (See fig. 9.) This space contains only a few glands and areolar tissue.

tion it was difficult to separate the auricle from the pleura. Injury to the mediastinal contents is one of the greatest dangers in the operative technique of pneumectomy.

The pleura is a mesoblastic product like the peritoneum and meninges, or according to Waldeyer and His a hypoblastic product. It is composed of a thin fibrous layer covered with endothelia. It reacts rapidly to irritants, but is not so active in its reproduction as the peritoneum. It is a closed sac completely lining the chest wall and enveloping the lung except at its hilum and is divided into parietal and visceral laminae. The pleura pulmonaris envelops and is firmly attached to the lung; it has depressions lining its fissures. The pleura costalis is attached to the ribs by a layer of connective tissue. In health it is practically impossible to separate the pleura from its attachment to the rib without opening its cavity. In disease it is often very much thickened and can be readily pulled off without the danger of pneumothorax. The pleura mediastinalis is attached to all of

Fig. 6.—Through eighth dorsal vertebra. 8th D.V., eighth dorsal vertebra; 7th D.S., seventh dorsal spine; Sc., scapula; St., sternum; D.Ao., descending thoracic aorta; V.A.M., vena azygos major; Es., esophagus; P., pericardium; Up.L., upper lobe of lungs; Lo.L., lower lobe of lungs; Mid.L., middle lobe of right lung. The pleura is indicated by heavy lines.

The middle mediastinum is the enlarged central portion which contains the pericardium and its contents, the phrenic nerves and accompanying vessels, the arch of the azygos veins and the roots of the lungs with their bronchial glands. The posterior mediastinum is situated between the pericardium, the diaphragm and roots of the lungs in front, and the spine behind. It contains between its pleural layers the descending thoracic aorta, the esophagus, the azygos veins, the thoracic duct and the posterior mediastinal glands. We must be mindful that the lower half of the superior vena cava is in the middle mediastinal space close to the trunk of the pulmonary artery and vein on the right side and must not be included in the ligature nor torn in separating the adhesions at the hilum of the lung. The right auricle is also endangered in this position and has been injured in experimental pneumectomy on animals. While separating an adherent diseased lung in a cadaver I tore directly into the auricle; after recognizing the condi-

tion the important structures of the mediastinum, the esophagus, trachea, pericardium, vagus nerves, innominate artery, superior vena cava, phrenic, etc. These attachments are practically the same on both sides. The pleura is intimately attached to these structures and can not be removed without a careful dissection. In separating a lung adherent in the mediastinum great care must be taken to keep on the pulmonary side of the adherent pleura, as there is danger of rupturing important mediastinal structures; further, the two pleuræ may be adherent and in separating them the other pleural cavity might be opened. This would most likely occur between the esophagus and the aorta, in front of the seventh, eighth or ninth vertebral bodies, or on a level with the third interspace in front. (C. Jannesco.) (See Figs. 10 and 11, showing extent of pleura. See Fig. 9, showing approximation of the pleuræ at the seventh, eighth and ninth vertebræ.)

When the pleura is deflected from the mediastinum

above, at the apex, it is attached to the innominate vein or the scalenus anticus muscle and further out to the subclavian artery and brachial plexus. The upper curve is flattened or concave in the center; it extends to a level with the neck of the first rib, but it is about three-fourths of an inch above the inner end of the clavicle. The attachment to the innominate vein and subclavian arteries are important factors in pneumectomy for apical disease, as adhesions are almost certain to exist. Visceral and parietal adhe-

sions of the pleura at this point occasionally produce a paralysis of the abductor muscles of the vocal cord on that side and the symptoms of laryngeal paralysis.¹⁰

The lower limits of the pleura are somewhat variable; on the right side in front it is attached to the sixth costal cartilage, the sixth space or the seventh rib and cartilage. From here it passes outward and downward to the eighth, ninth, tenth and eleventh ribs in an undulating and irregular manner and to the head of the twelfth rib and its vertebra. It often

extends an inch to an inch and a half below the twelfth rib, and even below the costal arch along the margin. This occurs most frequently upon the left side, as on this side it is as a rule five-eighths of an inch lower all around than on the right. (See Figs. 10, 11.) The pleura diaphragmatis is deflected from these attachments and completely covers the diaphragm except at the mediastinum; it is thin and firmly attached. The sternal attachment of the pleura varies; it recedes gradually from the center at the lower margin of the fifth space on the right side; it recedes more abruptly from the fourth rib on the left side, exposing the pericardium in the fifth interspace immediately to the left of the sternum. The pericardium may be opened in this position without interfering with the pleura. The anterior attachment of the right pleura often extends to the left of the median line and even to the left margin of the sternum. In normal condition the visceral and parietal pleurae are in close contact; effusion, hemorrhage and pneumothorax may change the positions.¹¹

Fig. 9.—X.A., xiphoid appendix; C.I., clavicle; T.S., triangularis sterni; I.M.A., internal mammary artery; D., diaphragm; P., pericardium; a., line indicating usual position of pleura; b., dotted line indicating unusual position of pleura.

The lungs.—The lung is an irregular, pyramidal semi-cone, concave in its center or hilum formed to the mediastinal contents; concave on its under surface for its adaptation to the diaphragm; it is convex and undulating in its entire outer surface. It does not extend to the limitations of the pleural cavity in many positions, particularly at its lower margin. The lower margin of the right lung starts at the cartilage of the sixth rib; it passes obliquely outward and downward to the seventh interspace in the mammary line and then almost vertically backward to the end of the eleventh rib. On the left side it is about three-eighths of an inch lower than on the right except in the incisura cardiaca, where the pericardium is exposed. It can be seen in comparing this margin with the lower boundaries of the pleura that the latter extends from one to one and one-half inches below the border of the lung. Sappy claims that the lung extends as far as the border of the tenth rib behind and only to the fifth rib in front on the right and to the sixth on the left side. The general impression regarding the thickness and shape of the lower lobe

¹⁰ Fowler and Godlee.

is erroneous, as it is believed to extend almost inward from the margin described, while in reality the under surface is represented by an irregular conical excavation (formed by the diaphragm) extending from its base one inch to the inner side of the lower boundary of the lung all the way around up to a level with the fifth rib in the center near the hilum of the lung. (See Fig. 12.) The degree of elevation of this cone is changed in pathologic conditions. In intrapleural effusions it may be depressed to a level with the eighth interspace. (See Figs. 10, 11.) With subphrenic pathologic products it may be elevated to the third interspace; in explorations with the needle the diaphragm may be punctured and the location of the exudate miscalculated, as the following case illustrates:

J. C., male, age 44, butcher; had suffered from dysentery for three weeks; was attacked with severe pain in the right side near the costal arch; this was rapidly followed by chills and fever, temperature reaching 105.3 degrees. Patient rapidly assumed a typhoid condition, low muttering delirium, dry tongue, tremor, etc. When the author saw him in consultation the dullness extended to the nipple in front and an inch above the angle of the scapula behind; there was a slight

Fig. 10.—Front of chest, showing relation of lungs and pleura to chest wall. 1 to 11, ribs; Cl., clavicle; D., diaphragm; Di., insertions of diaphragm; Ao., aorta; Ap., pulmonary artery; X, incision cardiac; X X, pericardium in contact with chest wall; Ls., upper lobe of lung; Lm., middle lobe of right lung; Li., lower lobe of lung.

deviation with change of position, there was bulging of the intercostal spaces, and the line of dullness extended two inches below the costal arch. The diagnosis of hepatic abscess with subphrenic and intrapleural rupture was made. An exploratory puncture in the seventh interspace, scapular line, first, on withdrawing the piston gave a clear fluid; the needle was introduced an inch further and the syringe filled with pus; diagnosis was changed to subphrenic, hepatic abscess. Operation proved the correctness of the latter diagnosis. The fluid first withdrawn was the secretion from the inflamed diaphragmatic pleura.

The apex of the lung is blunt and shows a depression where it is adapted to the subclavian artery, from which it is separated only by the pleura. The right lung is divided into three lobes by two fissures, the left into two lobes by one fissure. The great fissure in the right lobe separates the lower from the upper and middle lobes, and extends from beneath the second dorsal spine at first longitudinally outward and then obliquely downward to the lower border of

the lung opposite the middle of the sixth costal cartilage, and usually passes below the nipple. (See Figs. 13, 14.) The middle fissure originates about the middle of the great fissure beneath the junction of the fourth interspace with the middle axillary line and

Fig. 11.—Back view of chest, showing relation of lungs and pleura. 1 to 11, ribs; Tr., trachea; D., diaphragm; Pl., Pleura; Lm., middle lobe of right lung; Li., lower lobe of lung.

passes almost horizontally forward following the line of the fourth rib to the fourth costal cartilage. It separates the upper from the middle lobe. These fissures extend almost to the hilum of the lung. (See Fig. 15.) In disease the pleura lining the fissure becomes adherent, obliterating the fissures; not infrequently these fissures are the seat of circumscribed serous and purulent pleuritic effusions and are mis-

Fig. 12.—The diaphragm seen from behind. 1, right side of tendon; 2, left side of tendon; 3, right crus; 4, left crus; 5, origin from ribs; A, aorta; E, esophagus; P, pericardium; R.A., right auricle.

taken for cysts and abscesses of the lung. The fissure in the left lung corresponds to the great fissure of the right except that it passes a little higher in front at the cardiac margin of the lung. (See Figs. 16, 17.)

The pleura covering the lung is thin and firmly adherent. Anomalies as to the number of lobes and fissures are not uncommon, although the absence or non-development of a lobe is very rare; the most frequent anomaly is the absence of a fissure. Accessory lobes in the right lung have been recorded. In the dog as many as six have been found.

The right is the larger lung. An irregular notch in the left lung exposes the pericardium and gives the area of precordial dullness, which is irregularly triangular in shape; its first point of the base is at the middle line of the sternum opposite the fourth costal cartilage; the apex of the triangle is at the point of the apex beat, and the second point of the base is at the junction of the ensiform cartilage and the body of the sternum. The hilum or root of the lung is situated in a depression at about the middle of the lung between its apex and its lower margin about equi-

divisions of pulmonary veins and the pulmonary artery. The root of the right lies behind the superior vena cava and part of the right auricle. The vena azygos arches over it to enter the superior vena cava. The root of the left lung passes below the arch of the aorta and in front of the descending aorta, appearing to come out of the hook formed by the aorta. It is situated a little nearer the anterior wall of the chest than the right. The phrenic nerves pass in front of the roots on both sides and the pneumogastric behind. The bronchi are in the same relative position, posterior to the large vessels; they can therefore be ligated in front separately from the bronchus in pneumectomy. The vena azygos must not be included in the ligature and must be carefully separated from the adhesions to the lung, so that the root of the lung can be brought well forward for ligation.

Fig. 13.—Right side of chest. P1, spinous process of first thoracic vertebra; P12, spinous process of twelfth thoracic vertebra; 1 to 12, ribs; M, nipple; Ls, upper lobe of lung; Ln, middle lobe of lung; Li, lower lobe of lung; Pl, pleura.

distant from its anterior and posterior borders; it is occasionally nearer the anterior. The root is composed of the bronchus and its subdivisions, the large blood vessels, nerves, lymphatics and glands, surrounded by areolar tissue and reflections of the pleura; the root is on a line with the fifth, sixth and seventh dorsal vertebrae and almost directly behind the fourth costal cartilage and third interspace, on a line with the longitudinal fissure. The order of arrangement in the root (see Fig. 18), on the right side from above downward is, first, the pulmonary artery and its subdivisions; a little below that level and just behind is the eparterial bronchus; lower is the main bronchus behind and the pulmonary vein in front and a few smaller branches below; the left auricle presses in close to the bronchus behind and the right auricle a little lower in front. The order of arrangement in the root on the left side from above is, pulmonary artery and subdivisions, the bronchus and sub-

Fig. 14.—Left side of chest. P1, spinous process of first thoracic vertebra; P12, spinous process of twelfth thoracic vertebra; 1 to 12, ribs; M, nipple; D, diaphragm; Pl, pleura; Ls, upper lobe of lung; Li, lower lobe of lung.

The trachea and bronchi.—The trachea which has from fifteen to twenty cartilaginous rings measures four to four and one-half inches in length and three-fourths to one inch in diameter; it is situated in the central portion of the mediastinum; the arch of the aorta passes across it in front just above its bifurcation. (See Fig. 19.) It divides into two bronchi, the right and left, on a line with the fifth dorsal vertebra, which lead to the corresponding lungs. The right bronchus is about one inch in length; it is shorter and wider than the left, and in direction is more continuous with the line of the trachea (Aeby); in size the transverse section of the tubes is in proportion of 100 to 78. The right is composed of six to eight cartilaginous rings, while the left, which is two inches in length, has nine to twelve cartilaginous rings. The rings are thin and cover about two-thirds of the circle of the bronchus, the remainder behind is membranous, resembling the trachea in this par-

ticular. The right bronchus gives off a branch to the upper lobe about an inch from the margin of the trachea. The external covering of the larger divisions of the bronchi is made up of connective tissue and a few muscle fibers. The connective tissue is greater behind, as it takes the place of the cartilage in that portion of the circle. This covering can not be peeled off the bronchus without laceration, rendering it impossible to make a "cuff" when the bronchus is amputated, as we do in amputation of the appendix. The mucosa is a thin, delicate membrane made up of lymphoid cells and ciliated epithelia. The submucosa which secures the mucosa to the cartilage is thin and friable and easily destroyed with pressure. It can not be peeled from the inner surface of the bronchus, nor can it be invaginated for the purpose of producing occlusion of the bronchus after pneumectomy. The histology of its method of closure will be described in the experiments.

process of combustion; they believed the action took place in the lungs, but admitted that it might be in other organs of the body. It was later shown that the quantity of oxygen consumed is generally much less in cold-blooded than in warm-blooded animals. Most insects are marked exceptions to this rule, as they have a metabolism equal to that of the larger mammals. The respiratory exchange in warm-blooded animals is influenced by age, size of body, external temperature, muscular activity, rest, digestion, hunger and hibernation. Cold increases and heat lessens the respiratory exchange. It is the reverse of what has been observed in cold-blooded animals. It was illustrated by Levoisier and Seguin, who showed that a man at rest at a temperature of 32.5 degrees absorbed in an hour 34.49 grams of oxygen, but at a temperature of 15, 38.31 grams of oxygen. Exercise increases the absorption of oxygen. (See Schaefer's Physiology, London, 1898). The hyperpnea following exercise is

PHYSIOLOGY OF RESPIRATION.

Respiration is essentially the intake of oxygen and the output of carbon dioxide by living cells. There are but two acts in the process, the external, the exchange of gases in and out of the blood; and the internal, the exchange from the blood to the cells. Mayow in 1668 discovered the real function of respiration, and declared that it was the absorption of nitro-aerial gases (oxygen)¹¹. He also showed its similarity to combustion. Hale showed in 1726 that "noxious vapors were exhaled,"¹² and Black¹³ showed these gases to consist of a "fixed air," carbon dioxide. Priestley, 1772, demonstrated that plants restored the property of supporting animal life to air which had been vitiated by animal respiration or by combustion. Lavoisier and Laplace, 1777, taught that animal heat was the result of the oxidation of the tissues and was a

not due to excess of carbon dioxide in the blood as the result of increased metabolism, as the blood contains more oxygen and less carbon dioxide than during rest.¹⁴ It is probably due to some product of muscular activity which is absorbed by the blood and carried to the medulla, there to stimulate the respiratory center. Tartaric acid injected into the blood increases respiration; sodium hydrate (n: 1 sol.) diminishes respiration.¹⁵

A man at work absorbs 91.2 grams of oxygen an hour, while at rest he absorbs 38.3 grams an hour at a temperature of 15 degrees C.¹⁶ The carbon dioxide eliminated by a man at rest, asleep, is 161.6 c.c. per hour. During a walk at three miles an hour, it is 851.2 c.c. an hour.¹⁷ The percentage of carbon dioxide in the air exhaled is not changed, but the volume of air is increased.

Influence of food.—The ingestion of a meal upon respiratory exchange causes a marked intake of oxygen and output of carbon dioxide, due to the chemical changes which take place in food during digestion and absorption, and the increase of muscular and glandular activity of the alimentary tract. Smaller animals have a greater respiratory exchange than larger ones, other things being equal.

Influence of day and night.—There is a marked difference in the quantity of carbon dioxide produced between day and night. The increased exchange reaches its maximum from 11 A.M. to 1 P.M., and its minimum from 8 to 9 P.M.¹⁸ The respiratory exchange is greater in the young than in the aged per kilogram under the same conditions.¹⁹ Amphibia respire through the skin and mucosa of the alimentary tract, and in some this respiration is greater than that of the lungs. Cutaneous and alimentary respiration in mammals has been a field for considerable controversy, but it is the consensus of opinion that respiration takes place through the skin and alimentary canal. (See Cruikshank, Experiments on the insensible perspiration of the human body, showing its relation to respiration, 1871).²⁰

Fig. 16.—Outer aspect of right lung. U.L., upper lobe; M.L., middle lobe of lung; L.L., lower lobe of lung.

The respiration of fetal life, or exchange of carbon dioxide and oxygen, is very much less than in adults, about the proportion of 1 to 100.²¹ The respiration of the embryo in the egg of fowls and snakes takes place through the shell. If the egg is kept in a warm atmosphere of hydrogen for more than twenty-four hours the embryo ceases to live. The development of the embryo is neither hastened nor delayed if the egg is kept in an atmosphere of oxygen.²² This is in consonance with the exchange of oxygen in pulmonary respiration.

The amount of respiratory exchange in animals under normal conditions is not augmented by an increase of oxygen in the inspired air, but under pathologic conditions where the respiration is interfered

with and where the blood is abnormally venous, an increase of oxygen in the air inspired produces an increased exchange of gases.²³ This is a physiologic indication for the clinical use of oxygen in certain pathologic conditions of the respiratory apparatus, as pneumonia, compression of the lung, etc., and is also a positive indication for the administration of oxygen by inhalation after all operations which diminish the respiratory area of exchange.

The inhalation of air with a diminished quantity of oxygen produces marked symptoms, as observed in mountain climbing and balloon ascension. They are due to anoxemia, as was shown by Jourdanet.²⁴ The effect produced by air vitiated by repeated respiration is due to the deficiency of oxygen and the presence of carbon dioxide. The hyperpnea is due to the excess of carbon dioxide and not to the deficiency of oxygen. When the carbon dioxide exceeds

Fig. 17.—Outer aspect of left lung. U.L., upper lobe of lung; L.L., lower lobe of lung.

3 per cent. the hyperpnea is appreciable; at 10 per cent. it is marked; the frontal headache is due to the excess of carbon dioxide. When the oxygen is diminished to 12 per cent. the hyperpnea is appreciable and is excessive at 6 per cent.²⁵ Warm-blooded animals confined in a limited quantity of air die from want of oxygen and the blood is venous. The lack of oxygen produces its effect before the accumulation of carbon dioxide is sufficient to produce poisoning. Death takes place when the oxygen is reduced to 3 per cent. and the carbon dioxide increased to only 15 per cent. The fatal amount of carbon dioxide is 25 per cent.

The respiratory exchange in children and animals immediately after birth is very much less than later in life; this explains the fact that at this time they may be restored by artificial respiration a much longer time

after respiration has ceased than could be accomplished later in life. The increase of respiration during exercise does not seem to be due to an increase of carbon dioxide or lack of oxygen in the blood, but to the accumulation in the blood of some product of muscular activity. If the exertion be continued its effect ceases, the pulse becomes slow, the respiration less frequent, and the man is said to have his second wind, after which the same degree of exertion may be continued with comparative comfort for a long time.

The quantity of air exchanged in each respiratory act is a matter of great importance from a medical as well as a surgical standpoint. What is the minimum tidal exchange which is consistent with life in man

Fig. 18.—From Morris' Anatomy.

and what is the minimum of healthy lung tissue that will permit of that exchange? The tidal air in each respiratory act, in rest, is 114 to 196 c.cm., and 262 to 360 c.cm. during exercise.²⁶ The complementary air (the deepest inspiration) is 1722 to 1804 c.cm. (Hutchinson). The reserve air which can be expelled after an ordinary expiration is 1148 to 1804 c.cm. The residual air (mean) which remains in the lung after a forced expiration is 672 c.cm.²⁷ The vital capacity, quantity of air exchanged between the extremes of inhalation and exhalation, is 3558 c.cm. (mean for 1923 men).

A comparison of these figures shows what a great reserve respiratory power we have, and explains with what ease respiration may be carried on with a large proportion of the respiratory tract functionless. Our extreme capacity is 3558 c.cm.; in an ordinary exchange it is from 114 c.cm. at rest, to 360 c.cm. in exercise, therefore the extreme capacity is equal to at least ten times the quantity of ordinary exchange. Pathologically we recognize that with one lung entirely disabled by pleuritic effusion and the capacity of the other lung greatly diminished by displacement of the mediastinal septum, the respiratory exchange is still ample to sustain life. These physiologic and pathologic facts prove that with our surgical technic sufficiently advanced an entire lung may be removed, as the body can dispense with it.

The respiratory metabolism does not appear to be affected by the frequency of respiration except, as Pflüger has shown, to the extent of the increased demand made by the simple action of the respiratory muscles. The mean carbon dioxide elimination at seven respirations per minute in fifteen minutes is 7.836 grams, while in the same individual at sixty respirations per minute it is 7.868 grams. The conclusion therefore is, that the respiratory activity is determined by the needs of the tissues and not by the amount of oxygen carried to the blood. The temperature of the inspired air in man is raised to that of the body before it reaches the smaller bronchi. The volume of expired air is 1/50 less than the inspired. The volume of oxygen in arterial blood in the dog was found to be 22 per cent. The volume of carbon dioxide in the blood varies greatly but is usually only about 1/5 or 30 volumes per cent. of what it is capable of holding when shaken in pure carbon dioxide, which is 150 volumes per cent. The proportion of oxygen in venous blood as compared with arterial blood is 5.43 per cent. in venous to 20.75 per cent. in arterial; carbon dioxide 61.8 per cent. in venous; 47.33 per cent. in arterial. The blood will not absorb an excess quantity of oxygen, no matter how great its excess in the air inhaled. The union is a loose chemic combination between the oxygen and certain constituents of the blood, principally the erythrocytes.²⁸ The hemoglobin in these erythrocytes is the absorbing element.²⁹ Nitrogen is merely held in solution. Carbon dioxide is held in chemic combination with the pigment of the red cells and the alkalies of the serum; and is also loosely dissolved in the blood. The proportion of loose to firm is as 2 to 3.5 (Prior). The alkalies of the blood are the most important constituents for holding in solution the carbon dioxide. The blood corpuscles contain about one-third of the total carbon dioxide held in the blood. The red cells contain 10 volumes and the white 2.5 volumes in 100 volumes of blood.³⁰

Causes of exchange of gases.—At a temperature of 0 and a pressure of 760 mm.: The air inspired contains 20.96 volumes per cent. oxygen; the air expired contains 16.00 volumes per cent. oxygen; the air inspired contains 0.03 volumes per cent. carbon dioxide; the air expired contains 4.00 volumes per cent. carbon dioxide; the air inspired and expired contains about the same volume per cent. of nitrogen, 79.01.

Experiments have not accurately demonstrated the cause of the exchange of gases in the lung. It is the

accepted provisional theory that the exchange of gases between the blood and the air in the lungs is effected by physical and chemic means, the most important of which is diffusion.³¹ The surface through which this diffusion takes place is 90 square meters, and through this there are diffused 300 c.c. of carbon dioxide and about the same quantity of oxygen per minute in ordinary respiration. The velocity of diffusion is proportionate to the density of the gas; therefore the velocity of carbon dioxide is about twenty times greater than that of oxygen (Zuntz). The question which concerns the surgeon in this relation is how much of the 90 square meters of this surface can be dis-

produce the free ingress and egress of air to the functioning portion and thus does not cause sufficient respiratory exchange.

The internal respiratory exchange, the exchange of gases from blood to tissue, is due to the action of the cells themselves, the tissues having great affinity for oxygen, which they even store up for future oxidation. They are constantly producing carbon dioxide, this can only continue for a limited period of time in the absence of oxygen. The various tensions of gases in the different fluids of the body bear an important relation to their exchange.

(To be continued.)

Fig. 10.—From Morris' Anatomy, showing relation of arch of aorta to trachea and bronchi.

pensed with suddenly and how much can be dispensed with slowly, the former by amputation or compression of the lung and the latter by disease processes? Clinical experience shows that one lung may be suddenly rendered entirely functionless without materially embarrassing respiration, as in pneumothorax and in hemothorax, and as I have demonstrated experimentally and therapeutically by nitrogen gas injections into the pleura. We find pathologically that one entire lung and a considerable part of the other may be rendered functionless by diseased conditions before the apnea becomes marked and distressing. The difficulty in respiration in the latter stages of tuberculosis is due to two causes: 1, to the diminution of the pulmonary tissue capable of performing its function; and 2, the principal one, to the restriction of the respiratory motions of the chest produced by the adhesions and the consolidation and cicatrization of the diseased portion of the lung. This defective motion does not

DIABETES MELLITUS AT THE MASSACHUSETTS GENERAL HOSPITAL FROM 1824 TO 1898. A STUDY OF THE MEDICAL RECORDS.

Presented to the Section on Practice of Medicine, at the Forty-ninth Annual Meeting of the American Medical Association held at Denver, Colo., June 7-10, 1898.

BY REGINALD H. FITZ, M.D.,
AND ELLIOTT P. JOSLIN, M.D.
BOSTON, MASS.

The examination of the records of the cases of saccharine diabetes treated in the wards of the Massachusetts General Hospital during the past seventy-four years was begun for the purpose of seeking evidence with regard to the pancreatic origin of this disease. (See *Yale Medical Journal*, 1898, iv, 275.) Since several hundred volumes were to be searched it seemed desirable to obtain at the same time information upon other points which might contribute to the

³¹ Text-book of Physiol., E. A. Schaefer, London, 1898.

statistics of diabetes. Facts of interest in diagnosis and treatment were elicited as the study progressed and this paper is offered rather as a historical sketch of the progress of a disease drawn from the original records than as an attempt to advance in any way our knowledge of the subject. Since diabetes mellitus was first sharply differentiated from diabetes insipidus early in the present century, the hospital records may be considered to be nearly as old as is our knowledge of the disease in question.

During these seventy-four years the total number of cases of diabetes mellitus treated in the medical wards was 172, but of these, 9 were readmitted, making 181 separate entries. The following table shows the variation in the number of such patients during successive periods of years and their proportion to the total number of cases treated during the same periods.

Period.	Total number of patients.	Number of cases of diabetes.	Per cent.
From 1824 to 1840	5,328	7	.13
From 1840 to 1855	6,136	16	.26
From 1855 to 1870	8,660	24	.27
From 1870 to 1885	11,690	39	.33
From 1885 to 1898	16,085	86	.53

It appears from this table that within the past thirteen years as many cases of diabetes were admitted to the hospital as in the previous sixty-one years and the per cent. in the past thirteen years in proportion to the total number of hospital entries has increased fourfold over that of the first fifteen years. This fact is not due to any recent increase in the number of beds open to this class of patients, nor, presumably to any considerable excess in the frequency of this disease in the region from which the hospital receives its patients. Whatever may be its cause this occurrence is to be regarded as evidence of the wholesome tendency of diabetics to place themselves under careful medical supervision for such length of time as shall permit suitable observations to determine the severity and controllability of the disease, that the future conduct of the patient may accordingly be regulated.

Of the 172 cases, 127 (or disregarding fractions, 74 per cent.) were males and 45 (or 26 per cent.) were females. The oldest patient was 73 years of age and the youngest 5 years, the average age of 161 patients being 33.4 years. The average age among 40 female patients was 39.1 years, being higher than that in 121 males in whom it was 31.4 years. The following table represents the time of life at which the disease began.

Age.	Number of cases.	Per cent.
From 0 to 10 years	3	1.8
From 10 to 20 years	15	8.8
From 20 to 30 years	41	24.1
From 30 to 40 years	43	25.3
From 40 to 50 years	29	17.1
From 50 to 60 years	28	16.5
From 60 to 70 years	11	6.4

Diabetes thus is shown to be a disease predominantly affecting the middle third of life, though sparing neither the child of five nor the senior of seventy-three.

But one of the patients was a negro, a further illustration of the rarity of diabetes in this race, although Tyson (*Practice of Medicine*, 1896, 751) has met with several instances. Ninety-seven of the patients lived in the United States, and 83 claimed this country as

their birthplace. Thirty-nine of the patients were born in Ireland, 11 in the British Provinces, 9 in England, 4 in Scotland, 7 in Germany, 2 in Sweden and 1 in Denmark. Forty-three of the patients were mechanics, 23 servants, 17 laborers and 13 farmers. Of merchants there were 5, and of clerks 7. There were 5 mariners and 4 teamsters. Although four of the patients were students there were but two professions represented, a clergyman and an artist being included among the entries. There were single or a few representatives of several other occupations, and conspicuous for its absence was that of liquor dealer.

In 42 cases the question of an inherited tendency to the disease was raised and this factor was stated to have been present in 10 patients and absent in 32. In one case the father died of possible diabetes and this disease was the cause of the death of a brother and his daughter. The brother of one diabetic patient fell upon the ice, striking his head and died of diabetes four days later. In three of the cases the symptoms of diabetes came on within a few weeks after severe injury.

One of these patients while working in a mill in July so strained his back by lifting a heavy weight that he was unable to accomplish much afterward on account of supposed weakness of the spine. In August the appetite became increased and in December he entered the hospital for treatment of diabetes. The second was buried in a sand bank three months before entrance and was taken out unconscious. Six weeks later thirst made its appearance as the first symptom indicative of the onset of the diabetes. The third fell fourteen feet and struck on the back of the head. He was unable to work for a fortnight. Very soon afterward he began to have great thirst, hunger, and frequent micturition of large quantities of urine. The disease began in a female patient one month after very hard work in caring for a sick sister. The possibility of contagion was entertained in the case of a servant whose mistress was suffering from a severe variety of diabetes.

Post-mortem examinations were made in 15 of the 47 fatal cases. As is usual in this disease no characteristic lesions were found. The liver generally was normal in appearance although sometimes enlarged and in one instance it was rather small. The kidneys as a rule were normal, were enlarged in one instance, congested and with fat drops in the cortex in another, enlarged and hemorrhagic in a third, enlarged and infiltrated with round cells in a fourth. The stomach was large in two cases and Brunner's glands were found "developed" in a case under the care of Henry I. Bowditch in 1848. The condition of the pancreas was not mentioned in seven of the cases. This gland was stated to be normal in five and small in three instances. In one of the three its tissues were not remarkable, in another there was a moderate infiltration of fat tissue around the head of the gland, and in the third the weight was recorded as an ounce and a half, the section showing a coarsely granular surface.

No attempt has been made to note the relative frequency and the severity of the various symptoms. Particular attention has been paid, however, to the records of the condition of the urine, since they furnish a valuable commentary of the progress of our knowledge concerning the methods of studying this secretion.

In the earliest volumes of the records especial importance was attached to the measurements of the

quantity of urine passed as compared with the quantity of liquids ingested, since formerly it was the belief that patients excreted more urine than they drank liquid. As an illustration the following table is copied from the record of a case.

TREATED IN 1861.

Date.	Water drank--Pints.	Urine voided —Pints.	Specific gravity.

It is noted, for instance, in Vol. i, that a patient with diabetes simplex from Dec. 2 to Dec. 11, 1821, ingested forty-five pints and seven gills, but excreted forty-five pints and four gills. The first patient who is recorded to have had diabetes mellitus entered the hospital in 1824, and during the first three days of his stay is credited with drinking twenty and one-half pints of fluid, and is charged with passing twenty-five pints of urine.

This doctrine of an excess of outgo of urine over income of fluids appears in 1847 in Watson's Practice of Physic (3d American Edition, p. 869) as a statement that the "quantity of urine secreted and voided is sometimes enormous, far more than could be supplied by the quantity of fluid taken as a drink."

Twenty years later, Harley in his work on diabetes says (p. 50), "diabetic patients generally pass more liquid than they take, about one-fifth or one-fourth more."

Lauder Brunton in 1879 (Reynold's System of Medicine, 1879, p. 387) opposes this view in the following words: "It has been said that the quantity of urine excreted by the patients is greater than that of their beverages, but this can hardly be the case, and the observations which seem to support this view have probably been made for too short a time, the apparent excess being most likely derived from water lodged in the system."

The difficulty of eradicating this erroneous idea is indicated by the fact that a recent graduate of the Har-

vard Medical School and of the Massachusetts General Hospital, seriously asserted that "it is perfectly well known that a person passes more urine than he drinks fluids." Such a view is based probably upon a misinterpretation of the physiologic teaching that more fluid is eliminated from the body in respiration and in secretion from the various glands than is taken in as liquid. In this connection it is interesting to note that a metabolism experiment in diabetes was made at the hospital in 1845. For it is then recorded that "in the last twenty-four hours ingesta were, solid 30 oz., liquid 54 oz. Total 84 oz. Egesta were, solid 8 oz., liquid 26 oz. Total 34 oz. Difference 50 oz."

The largest quantity of urine stated to have been voided in twenty-four hours was 576 ounces. The record of this patient is, "June 26, 1861, urinated thirty-six times; voided thirty-six pints. . . . It contained 3 per cent. of sugar, corresponding to 227 grains in one pint." Only six of 166 patients passed over 300 ounces in one day. The highest sp. gravity recorded is 1054, although repeatedly it was found above 1045. The highest percentage of sugar mentioned was 12.5 per cent. In many instances there was present between 9 and 10 per cent. of sugar.

The finding of sugar in the urine was determined in the first instance until 1851 by means of the taste. The physician in charge sometimes called upon the house physician to apply this test, although a positive statement to this effect is found only in 1844 and again in 1845. It is probable, however, that the patient was occasionally called upon to use this method, for in 1831 the statement appears, "on tasting, as directed to do by the physician . . . it was found sweet." This patient is credited also with the ability to make quantitative determinations in this way, for "he observed, however, that if he relapsed at any time, even in a very slight degree from a rigid animal diet, the urine was increased correspondingly in sweetness and quantity." In another instance it is stated that the urine is "less sweet after eggs." In general the patient at the time of entrance was able to make such positive statements as made apparent the condition of the urine. One "reports urine sometimes natural, at others sweet." It had the "sweetest taste," or was "sweetest to the taste." The urine had a "saccharine smell and taste," or presented a "sugary appearance on the shirt," or the "urine upon cloth leaves sticky and sparkling deposit." The intelligence of the lower animals sometimes aided in the diagnosis, for of one patient's urine it is stated that "flies gathered upon places moistened by it." Such everyday methods of diagnosis are still in use, for it is but recently that an office patient stated of her diabetic mother that her "clothes would rattle like starch, so sugary was the water, like brine on the floor."

These rude methods of testing the saccharine condition of the urine were supplemented in 1827 by evaporating the specimen. It is recorded "urine yesterday sixteen ounces, . . . seven ounces this morning, . . . sixteen being boiled about two remains (sic), resembling molasses, of saccharine smell and taste." In the following year, "urine seven pints, natural appearance, without sediment, not giving syrup on evaporation." It is stated also that eight ounces of urine yielded one ounce of syrup, and at the end of the record of the autopsy of a fatal case it appears that specimens of the saccharin matter and of the nitrate of urea prepared from the urine on dif-

ferent days by Dr. Chas. T. Jackson will be found in the cabinet of the Soc. for Medical Improvement, Nos. 566 and 567.

In 1833 we learn that "one quart of urine boiled to the consistency of thick molasses weighed two and one-half ounces. On the 12th the same quantity boiled as before weighed three ounces." This method was still in vogue in 1842 for "two ounces carefully evaporated gave about a drachm of clear extract of the color and consistency of treacle," and four years later the evaporating method still was employed.

In 1841 Trommer's test was made known (*Annal. der Chemie und Pharmacie*, 1841, xxxix, 360) and in 1842 the hospital records state that the "urine was unaffected by heat, nitric acid or aqua potassa." In this year the fermentation test also was first employed.

In 1846 the following letter from Dr. John Bacon, Jr., is entered in the records, and shows the results of his investigations for the purpose of determining the nature of the sugar to be found in diabetic urine. It seems worthy of reproduction as an illustration of the scientific methods employed even fifty years ago in the investigation of disease.

BOSTON, May 12, 1846.

DR. J. B. S. JACKSON.

Dear Sir:—The microscopic examination which I have made at your request, of the sugar from diabetic urine has afforded some results worthy of mention. The specimens of saccharine urine placed in my hands were from two diabetic patients now in the hospital. My first attempt was to obtain the sugar in a crystallized state by the evaporation of successive portions of the urine on slips of glass, both spontaneously and by the aid of a gentle heat. But the results obtained in this way were unsatisfactory from the difficulty with which this variety of sugar crystallizes, and the following process was substituted. The urine was evaporated over a salt water bath, to the consistency of a thick syrup, and drops of this, spread very thinly on slips of glass, were left to spontaneous evaporation. In the course of a few days the liquid disappeared, leaving on the glass little hemispherical grains of a white color (none of them as large as the head of a pin), either isolated or collected into mammillated crusts. With the urine of the male patient, Pettigrew, two or three days were sufficient for this purpose; that of the female patient, Gould, which appeared to contain less sugar in proportion to the other constituents, required more than a week's exposure.

The objects thus procured were prepared for the microscope by covering them with Canada balsam. Being now examined with moderate powers, each little grain resolved itself into a compact group of fibers radiating from a central point, many of their ends projected beyond the mass, but exhibited no distinct crystalline faces. This radiated structure, with a fine silky lustre, becomes distinctly visible to the naked eye in the larger grains, when they are covered with the balsam. The aid of the polarizing attachment to the microscope was now called in to decide the question as to the crystalline structure of the grains, when the rich and varied colors exhibited in the polarized light left no doubt of their really being groups of radiating acicular crystals. Among these masses of sugar there were noticed a few groups of more distinct crystal, not arranged like them in a stellate manner, and presenting entirely different appearances in polarized light. These are doubtless some of the saline constituents of the urine. As diabetic sugar is classed with that variety, to which from its abundance in the juice of ripe grapes the name of grape sugar is given, it became of interest to compare the appearance of the two under the microscope. Grape sugar is present in large quantity in honey, and is the variety formed from starch or from cane sugar by long continued boiling with dilute sulphuric acid. This variety is entirely distinct in its character from the common or cane sugar. A portion was prepared from honey and dissolved in alcohol, the solution, evaporated to a syrup and prepared for the microscope in the same manner as the diabetic urine, crystallized in groups of radiating fibers like the diabetic sugar, and presented similar appearances under the microscope, both with and without the polarizing attachment. An alcoholic solution of the diabetic sugar was also prepared, which crystallized in the same manner; a similar solution of cane sugar afforded no radiated groups,

but distinct prismatic crystals which gave fine colored rings in polarized light. Under the microscope the urine of both patients (before evaporation) is seen to contain great numbers of colorless globules, often connected in chains or groups of half a dozen or more. I made a cursory examination for urea, by evaporating an ounce of the urine from each patient to one quarter and adding an equal volume of nitric acid. Pearly crystalline plates of nitrate of urea soon made their appearance in both, showing urea to be present in considerable amount, but the quantity of urine operated upon was too small to allow of a correct determination of the amount.

Yours respectfully, JOHN BACON, JR.

Although Moore's test had been made known in 1844, the first mention of its use in the hospital was in 1851, when the following record appears "glucose strongly marked on the addition of heat and liquor potassæ."

In 1852 Dr. Bacon determined, by what means it is not stated, that the per cent. of sugar in a given urine was 4 per cent. and two years later the fermentation method was employed for ascertaining the percentage.

The breath of diabetic patients first attracted attention in 1835, when a man entered the hospital with a note from his physician stating that it had a "peculiar sour smell." The observation made of this patient while in the hospital was of "a curious smell in breath which he has had since entrance." In three cases the breath is stated to have the odor of new milk. In 1846 it is noted of one of these "odor of breath considered by some of aromatic sweetness." Other expressions are in 1846 "odor of boiled milk;" in 1848 "ward distinctly tainted with smell peculiar to diabetes," "fruity odor;" in 1869 "sweet chloroform-like smell in neighborhood of patient's bed."

That the acetone odor of the breath then was attracting general attention is apparent in 1847 from the statement made in Watson's Practice (op. cit. p. 868) that "according to Dr. Prout the scent somewhat resembles that of sweet hay, but to my nose it is more like the smell of certain apples or rather of an apple chamber." He attributes the peculiar odor to the sugar. In 1866 in Harley on Diabetes (op. cit.) there is no mention of acetone or of diacetic acid, although Petters (*Prager Vierteljahrsch.* 1857, iv) several years before had attributed the coma of diabetes to the former agent.

Acetone was sought for in the breath of 19 cases, and in the urine of 24 cases. Its presence was indicated by the odor in 16 of the former, and by chemical tests in 14 of the latter series. It is interesting to note in connection with the result of recent investigations on the increase of acetone in consequence of a change to an absolute proteid diet, that the records state in 1894 that the "acetone smell has been more since disappearance of sugar than at any other time." Ten days later, however, without any change in diet there had been no return of sugar and no smell to the breath.

The ferric chlorid reaction, which, when positive, is considered generally to be evidence of the presence of diacetic acid, was sought for in 22 cases and found in 13. Albuminuria was present in the urine in 67 cases and was absent in 60 cases. Casts were found in 36 cases.

In four instances only is there a record of the examination of the feces. In 1844 a patient reported that his "food frequently passes away in lumps undigested" and fat is reported as absent in the stools of three patients.

In six cases there was tinnitus aurium and two patients had sciatica. Sexual power is noted as absent

in 9 cases and present in 4. The catamenia were present in 11 cases and absent in 9. Jaundice is mentioned to have occurred in five cases, and three of these patients died in the hospital, one of pneumonia and one of atrophied pancreas. Syphilis is stated to have existed in one case. Diabetes and myxedema coexisted in one patient and in another diabetic there was a tumor of the thyroid body. Three of the patients suffered from gangrene of the toe, a fourth had a gangrenous slough of the tissues of the leg, and a fifth died with a carbuncular-like inflammation of the thigh. Three of the patients had abscesses, one being of the hip, another of the wrist, both cases ending fatally. The third abscess was of the jaw, but the patient grew better. In one case there was a round ulcer of the toe, which improved under treatment.

The records afford some evidence concerning the duration of the disease, which in one case is stated to have existed for twelve years, while three patients had suffered but two weeks. Of the latter, one died, one was relieved and one unrelieved. The average duration was one year and a half.

The length of the illness in the fatal cases is indicated in the following table:

DURATION.	NUMBER OF CASES.
From 0 to 1 year	27
From 1 to 2 years	7
From 2 to 3 years	3
From 3 to 4 years	1
From 4 to 5 years	0
From 5 to 6 years	1
From 6 to 7 years	1
Unknown	7
	47

These cases, necessarily those of grave diabetes, thus ended fatally in nearly three-fourths of the number in which this point could be determined within one year after the disease made itself manifest, and within two years in nearly seven-eighths of the entire series. That diabetes may prove fatal at the end of a longer period of time, from 6 to 7 years as in one instance, is attributable to the well known fact that cases of mild diabetes may become suddenly severe, and that the symptoms of this disease may for a while disappear to return at a later period. An illustration of the latter condition, one which may be called recurrent diabetes, is to be found in the record of a patient who was in the hospital in 1862. In March, 1861, he suffered from cough with abundant yellow expectoration. In the latter part of the month the thirst increased and became excessive; the patient drank freely and passed large quantities of pale urine. The appetite failed and there was progressive debility. At the end of four months the quantity of urine became normal. The patient remained apparently well until the following February, when excessive thirst, polyuria and debility returned, and it was observed that the urine left a sticky and sparkling deposit on cloth. Another instance of recurrence is noted in 1866. Two years previous to the entrance of this patient he observed that an abnormally large quantity of urine was being passed in the twenty-four hours and that the thirst was excessive. These and other symptoms continued for three months and then disappeared without treatment. At the end of eighteen months, however, they returned, accompanied by general weakness and faintness. It is recorded that the house physician tasted the urine of this patient.

Of the 172 patients 47 or 27 per cent. died. The mortality among the 127 male patients was 39 or 30.7 per cent.; of the 45 female patients 8 died, a mortality of 17.7 per cent. The death rate among the males

thus proved nearly twice as high as among the females. The following table illustrates the variation in the rate of mortality during successive periods of years.

Period.	No. of cases.	No. of deaths.	Percentage of deaths.
From 1824 to 1840	7	1	14
From 1840 to 1855	16	7	44
From 1855 to 1870	24	5	20
From 1870 to 1885	39	11	28
From 1885 to 1898	86	23	27
From 1824 to 1898	172	47	27

It has previously been remarked that from 1824 to 1885 there were treated 86 cases, the same number of cases as in the period from 1885 to 1898. It is certainly noteworthy that in each of these intervals there was an average of 27 per cent. of fatal cases, which again was the average mortality rate of the cases treated throughout the entire period from 1824 to 1898. It might be thought from the inspection of this table that the method of treatment was superior from 1824 to 1840 and from 1855 to 1870 and that in the intervening years it was inferior. The information on this point later given affords no justification for such an inference.

Although it appears from the study of the records that most cases of grave diabetes die within a year or two of the onset of the disease and that 27 per cent. of all cases are fatal, some evidence has been obtained with regard to the prognosis in the individual case. Heredity appears to have less importance than is usually assigned to it. Of ten cases in which heredity may have been of etiologic significance three died, while of thirty-two cases in which heredity had no influence eight died. Thus the percentage of deaths was merely a trifle higher in those cases in which an inherited tendency to diabetes may have played a part than in those in which no such influence existed.

The time of life at which the patient suffers from the disease appears to be of greater prognostic importance, as may be inferred from the following table:

Age.	No. of Cases.	Deaths.	Per cent.
From 0 to 10 years	3	1	33
From 10 to 20 years	15	3	20
From 20 to 30 years	41	14	34
From 30 to 40 years	43	13	30
From 40 to 50 years	29	4	14
From 50 to 60 years	28	5	18
From 60 to 70 years	11	5	45
	170	45	

Thus about one-third of the patients suffering from diabetes during the first ten years of life and between the ages of 20 and 40 years die, and nearly one-half of the cases between 60 and 70 years prove fatal. The number of cases of diabetes in young children, however, is so small as not to be of much value in generalizing. The high rate of mortality after the age of 60 is due, possibly, only indirectly to the diabetes, the patients perhaps being unable to resist the effects of other disease, even if mild, in the presence of so grave an affection.

Thirty-eight of the 47 fatal cases died comatose, the coma lasting one day in 10 cases, two days in 14 and three days in 5 patients. In the remaining 9 cases the duration of the coma was not to be determined. The frequency of the coma in relation to the age of the patient is indicated in the following table:

Age.	No. of cases.	Deaths from coma.	Per cent.
From 0 to 10 years.	3	1	33
From 10 to 20 years.	15	3	20
From 20 to 30 years.	41	12	29
From 30 to 40 years.	43	9	21
From 40 to 50 years.	29	3	10
From 50 to 60 years.	28	4	14
From 60 to 70 years.	11	3	27

The suddenness of its onset in certain instances is apparent from the record of a patient in 1828 who was able to leave the hospital for a few hours, at the end of which he became comatose and died. In 1846 another patient absented himself from the hospital without leave and became intoxicated; two days later he was comatose and died at the end of another two days. On the other hand, a third patient while in the hospital became intoxicated, had no coma and lived.

It is to be observed that of twenty fatal cases of diabetes there was present chronic nephritis in six, pulmonary tuberculosis and carbuncle or gangrene each in three, myocarditis in two and pneumonia, pleurisy, cerebral thrombosis, alveolar abscess and atrophied pancreas each in one. A patient with diabetes suffered at the same time from acute catarrhal cholangitis, acute rheumatism and chronic bronchitis.

The study of the records of these cases affords some evidence relating to the prognostic value of the presence of acetone and diacetic acid. Although the odor of acetone was present in the breath of 12 out of 14 fatal cases, that is, in more than 85 per cent., and in the urine of 6 out of 9 fatal cases, namely 66 per cent., in which the records show that attention was directed to this point, it was present also in the breath of 4 out of 5 non-fatal cases, 80 per cent., and in the urine of 8 out of 15 non-fatal cases, 53 per cent. It is evident from this comparison that the presence of an acetone odor in the breath or in the urine throws but little light upon the severity or mildness of the disease.

The ferric chlorid reaction was present in 6 out of 8 fatal cases and in one-half of the 14 non-fatal cases in which it was sought for. This evidence, so far as it goes, therefore, is in support of the view that this reaction has a somewhat serious significance.

It is interesting to note that in the earliest days of the hospital the improvement of the patient's condition was based upon an increase in weight.

It is to be remembered that John Rollo (Notes of a Diabetic Case, 1897) first ascertained that an animal diet not only decreased the quantity of urine, but also diminished the amount of sugar. The diet, therefore, from 1824 to 1840 was based evidently upon this discovery and the first diabetic patient in the hospital was fed on "animal food and bread in small quantities. Only one potato (*sic*) at dinner." Later molasses, beer and apples were excluded from his diet. In 1827 a patient's fare consisted of two eggs, at a meal, meat, milk, butter and salt. Such a diet, however, was not exclusive, for mention is made that vegetable food and sugar were not to be taken, but rice and milk porridge were allowed. Toast water and broth were permitted, and crackers were given instead of bread. Thirst was quenched with chamomile tea or balm tea, and lemons also served for this purpose.

The unlimited use of liquids was not permitted, for one patient was allowed only a "teacup of liquid at meals." Another was given, "balm tea as little as will suffice," and it is stated of a third that he "thinks he has not drank all his allowance."

The first treatment the first patient received was a warm bath, and as the quantity of urine appeared to be less after the bath had been taken it was ordered to be repeated every other day. Warm salt baths also were used.

The advantages of exercise were appreciated at an early period, for one patient in 1831 was advised to ride horseback, and another was recommended to take as much exercise as his strength would permit.

Alcohol was given as early as 1828, when the physician in charge ordered, "let her take some brandy and water, taking one teaspoonful of brandy in hot or cold water, repeating it once in 3 or 4 hours if the effects are grateful." There is nothing in the record to show that its action was displeasing to the patient. The recent investigations of von Noorden ("Die Zuckerkrankheit und Ihre Behandlung," 1895, 146), show that this treatment has a sound scientific basis since one gram of alcohol is the equivalent of seven calories, while the same quantity of proteids and carbohydrates is equivalent only to four calories.

This patient was treated also with opium and "by error took following in A. M.

R Infus. Sennæ Comp., 3iij."

On the next day he "was uncomfortable in head with some depression of spirits." During this patient's stay in the hospital he was ordered powdered rhubarb and the infusion of rhubarb and magnesia; a trial was made also of uva ursi and of the sodium and potassium tartrate.

During the first fifteen years the treatment in general consisted of opium, either alone or with camphor and aloes. Cathartics were used liberally, and frequent mention is made of rhubarb, aloes, colocynth, senna, calomel, magnesium sulphate, castor oil and croton oil. Enemata were employed freely, some of them being especially designated "active." One patient who complained of nausea promptly received a dose of ipecac.

Among other drugs in use during this period were quinin and dilute nitric acid, the decoction of sumac and powdered guaiac.

Blisters and cupping often were used, and one patient "thinks opium and blisters have been followed by the greatest improvement." More severe counter-irritation was ordered sometimes, as appears from the record, "apply caustic issue on each side of the spine." In one case this application proved to be directly injurious.

During the period of high mortality, that is from 1840 to 1855, the following dietary is ordered: "Lean meat, with a small quantity of stale, dry or toasted bread, avoiding all fatty, farinaceous and saccharine articles. For drink, cold water and weak tea." The use of liquids continued to be restricted, although slippery elm tea now came into use. Alcohol was not given regularly, and blisters no longer were applied. Leeches appeared to serve in the place of the latter and of issues for it is recorded, "Leach (*sic*) bites now ulcerated."

Opium continued to be given, but not so largely as previous to 1840. Cathartics were prescribed with freedom, and the liberal use of calomel is suggested by the frequent records of spongy gums and myrrh mouth washes. Iron now was used in the form of the tincture of the chlorid or the carbonate. Other remedies employed were argentic nitrate, ammonium hydrosulphuret, ammonium carbonate, conium, hyoscyamus and valerian, aromatic sulphuric acid and

creosote. During this period the use of yeast was tried by McGregor (Watson's Practice, p. 872), who stated that it made the patients feel as if they were "on the eve of being blown up." A patient in the hospital was ordered to "take yeast 3ss. in milk *ter die*." This quantity was increased to an ounce daily and then was resumed and omitted at intervals during a month, the yeast being taken five-sixths of the time. The effect was not that mentioned by Watson, but a sense of constant nausea was the chief resulting complaint.

From 1855 to 1870 especial attention was paid to the selection of a suitable bread, and bran bread, stale bread, brown dyspepsia bread, toasted dyspepsia bread, ship biscuit and toasted ship bread were ordered. Butter, cabbage, cheese and greens were allowed, but shellfish and liver were excluded. Liquids at times were restricted, and cocoa was given somewhat frequently. Alcohol was ordered occasionally, and one patient, notwithstanding milk punch was prescribed *p. r. n.*, remained in the hospital but a single day, at the end of which he was discharged unrelieved. Opium was but little used, counter-irritants were discontinued and there was but little variety in the use of drugs. One patient received a half pint of iron rust water at dinner. To another in 1866 was given a half ounce of cod liver oil three times daily. As "she likes it and don't have enough," the dose was increased to three ounces three times daily. This maximum dose was reduced in consequence of the production of loose movements of the bowels.

From 1870 to 1885 gluten bread was used, but was discovered to contain 33 per cent. of starch. Patients were advised "to drink as little water as possible," but as much as four quarts of skim-milk were given daily. Opium and codeia were used frequently, but alcohol, blisters, baths and exercise were not advised as a part of the routine treatment. On the contrary, a large number of drugs were employed, including Fowler's solution, bromid of arsenic, antimony, bismuth, phosphate of zinc, phosphorus, bromid of potassium, iodid of potassium, sulphid of calcium, salicylate of sodium, hydrochloric acid, lactic acid, gallic acid, pilocarpin, chloral, ergot, pepsin, Wilbur's oil and Shaw's pill. One patient received what was called the glycerin treatment, instituted by Schultzen (Naunyn, "Der Diabetes Mellitus," 1898, 405). On the day after his admission he was given thirty-three ounces of glycerin and died comatose on the same day. The coma was accompanied by spasms, to relieve which ether was given, but the house physician apparently feared that the death might be attributed to the effects of the ether.

In the period since 1885, Soya bean bread has been added to the dietary, and fats are used with freedom. The use of water is frequently, by no means always, restricted, and the use of skim-milk gradually has lessened. Alcohol, baths and exercise, are not made matters of routine. Opium and codeia are more often used than before, and trials have been made with potassium citrate, lithium carbonate, jambul, salol, salicin, antipyrin and urethan. Saccharin occasionally is used. Up to this period comatose patients had been treated solely with stimulants and diuretics, and brandy, nitroglycerin and oxygen were given frequently at the onset of coma. The use of solutions of sodium chlorid or sodium bicarbonate in enema, subcutaneous injection or by transfusion was begun and eight

patients were thus treated. Although these patients died, as had those otherwise treated, it appears from the records that in certain instances life was somewhat prolonged. The patient's mind usually became clearer after the administration of the saline, and one person was aroused to such a degree that he is recorded to have said, "Oh! doctor, I'm glad you did that: I have not felt so well for a long time."

The practical outcome of this examination of the records of cases of diabetes treated at the Massachusetts General Hospital during the past seventy-four years can be stated in a very few words. The average mortality of saccharin diabetes has not changed materially, for it was the same in the past thirteen years as in the previous sixty-one years. The dietetic restrictions have undergone no essential alteration in this time. Opium is the only drug which has been persistently used in the treatment throughout this entire period.

DISCUSSION.

Dr. WEST—I have been much interested in the résumé of the large number of cases referred to by the reader of the paper. There were several points that struck me during the reading of the paper which I do not wish to discuss so much as to make inquiry about. First in regard to race. I notice the doctor said that no cases occurred among the negro race (Dr. Joslin: one case reported.) The small proportion might be due to the small proportion of negroes in that country. So far as my observation goes, living as I do in a country where there is a large proportion of these people, I never saw a case of diabetes in the negro race.

I would like to inquire too about the statistics in regard to the occurrence of diabetes among the Hebrew race.

The cases of diabetes that I have had in my practice have occurred in persons who were fleshy.

In regard to diabetes occurring as a complication of gout I have found in my experience gout and diabetes frequently associated.

Another point that I would like to inquire about is the rapidity of the fatal results in the cases of the young. Diabetes pursues a rapid course in the young persons, more than in the older. I noticed that albuminuria was found in about 60 per cent. of cases and yet the autopsy failed to show any kidney lesion. That seems to me remarkable. I should like to inquire also in what proportion of the cases was diabetes of cerebral origin.

Dr. TYSON—There is only one point I can treat which relates to the question of diabetes occurring in negroes. About three years ago I gave a clinical lecture and I made the statement that I had never seen a case of diabetes in a negro. There happened to be present a negro physician who had a large practice among negroes, and in the course of a few days I had three negroes referred to me with this trouble. I think, therefore, it is not unlikely that diabetes is more common in the negro race than it is supposed to be. My experience at that particular time satisfied me as to that fact. I have been interested in diabetes occurring in young children. Many cases occur in young children, but I can not find an explanation why. Diabetes is much more common among the Hebrew race than among Christians. It is also a much more common disease in males than in women.

Dr. BOND—I would suggest that the Hebrew race probably have this disease more than any other people on account of their love of high living. It is a well known fact that they eat largely of such foods that are irritating more than any other class of people. They are given to parties, they congregate together and have frequent and irregular meals. I believe it is from that fact that they have this disease more than any other people.

Dr. STOCKTON of Buffalo I rise to call attention to the historic value of the paper. I think this paper is a very useful illustration of the principle expounded this morning in the general address in medicine by Dr. Musser.

Dr. JOSLIN—In reading my paper much was necessarily omitted on account of lack of time. The printed article will contain answers to the preceding questions.

THE USE OF IRON AND OPIUM IN BRIGHT'S DISEASE.

Presented to the Section on Practice of Medicine at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY JAMES TYSON, M.D.

PHILADELPHIA, PA.

For some time I have been rather anxious for an opportunity to relieve myself on the subject of the administration of iron in the treatment of Bright's disease, the more especially as I feel somewhat responsible for the present, as I regard it vicious practice of indiscriminate prescription of this drug in the disease referred to: for I am one of those who in times past have taught that iron is a remedy indicated in almost every case of Bright's disease. Thus on page 138 of my book on Bright's Disease published 17 years ago, I say, "It may be laid down as a rule to which there are few exceptions, that the *continuous* use of some one of the preparations of iron is indicated," the word continuous being underscored in the original. Again on page 186, in speaking of the treatment of chronic interstitial nephritis, I say of drugs, "Iron is perhaps the most important and indispensable and may be given in the shape of the acetate or the well known Basham's mixture." I have learned since writing the above that there is a good deal of mischief done by iron in Bright's disease, and I am not sure that it would not have been better for many patients if the gallons of Basham's mixture which have been prescribed since Dickinson first suggested it over 25 years ago, had been poured into the street gutter rather than into the stomachs of the patients it was intended to benefit. It is an interesting fact confirming the statement already made that scarcely a patient ever comes to me in consultation or is sent from another physician who has not been taking Basham's mixture, and it is further confirmation that in a very large number of these cases it is given under the impression that it has some specific effect toward curing Bright's disease. It is needless to say that it was never suggested for any directly curative purpose, but simply as a remedy for the anemia which is so conspicuous a symptom in many cases and for this purpose it still is and always will be useful.

But not every case of Bright's disease is anemic, and as iron has no specific curative effect it is clearly not indicated in non-anemic cases. Nay more, it is often harmful. It is harmful by locking up secretion and checking elimination already restricted by the diminished functional activity of the kidney. The direct results of this are seen in headache and head-throbbing, associated with constipation and coated tongue to which the patients themselves often call attention and which appear much earlier in these cases than in persons who have integral kidneys. In such cases Basham's mixture or iron in any form may even precipitate uremic symptoms.

While anemia as determined by the appearance of the patient and more accurately by a blood count and hemoglobin measurement is the only indication for the use of iron, it is possible also to indicate in a general way the class of cases in which iron may or may not be useful. Thus it may be laid down as a rule to which there is almost no exception that iron is not indicated, and should not be prescribed in cases of acute Bright's disease. Iron is at best a remedy of slow operation so far as good effect is concerned, while

it is rapid in producing its harmful influence whatever that may be. In acute Bright's disease there is not generally anemia and where there is, it is of secondary importance to more urgent symptoms. It is trespassing on nature therefore and embarrassing other more urgent treatment to give iron in acute nephritis. On the other hand, after the acute symptoms have passed away and convalescence sets in iron is often very useful.

A second class of cases in which iron is contraindicated and is more frequently harmful, is chronic interstitial nephritis. The association in this condition of more general total destruction of tubular epithelium with restricted elimination goes to show that it is not unlikely that in parenchymatous nephritis acute and chronic the renal cells are capable of a certain degree of function even though they be cloudy and swollen. At any rate it is in chronic interstitial nephritis that iron is more promptly and dangerously harmful than in any other form of Bright's disease. It does happen that in advanced stages of this affection there is sometimes extreme anemia and it would seem that under these circumstances it might be used. And under such circumstances if at all it may. But even in this, representing as it does, the last stages of the disease, in which a dilated heart is staggering under a load it can barely carry and in which a last straw may either cause it to stop beating or furnish the spark to ignite a fatal uremia the drug is of questionable value.

The form of Bright's disease in which iron is best borne is chronic parenchymatous nephritis. And as this is apt to be associated with more or less anemia it becomes a most valuable remedy in overcoming this symptom. Even here the doses given are usually needlessly large. I hold that wherever iron appears in the stools for whatever cause administered this unabsorbed portion is useless, and as it is this which acting as an astringent causes constipation it is not only wasted but harmful. My practice is to determine the proper dose by an examination of the stools and if these are decidedly blackened, I hold that I am giving too much. On the other hand a slight coloration may be permitted as indicating that a sufficient dose has been attained.

A further explanation of the general use of Basham's mixture is the very common impression that this preparation of iron is diuretic. I am inclined to believe that this is an error, or at any rate it is no more diuretic than the bulk of water which constitutes its menstruum. That some diuretic action may be expected from this source is rendered reasonable by the fact that Basham's mixture and in fact any preparation of iron is commonly freely diluted. The ingestion and absorption of so large a bulk of water may be reasonably expected, by the increased intra-vascular pressure which it excites, to produce increased secretion of urine.

As to the second of the drugs mentioned in the title of my paper, I believe the dangers of its use are more generally appreciated, and yet I am confident that many a life is sacrificed by the injudicious use of opium. I believe, therefore, that a word of warning can not be out of place. That we should endeavor to understand the conditions contraindicating the use of opium in Bright's disease is the more important, because there are certain states in which opium has been held to be of signal advantage, namely, in the treatment of uremic convulsions. I regard the evidence in favor of the efficiency of hypodermic

injections of morphin in certain cases of uremic convulsions as altogether too conclusive to admit of denial, yet I am certain that death has not infrequently been precipitated by it, and when I tell you I have seen a fatal uremia induced by a couple of teaspoonsful of paregoric, I trust I convey to you an adequate idea of the dangers of this drug.

First, perhaps, it is desirable to know the conditions in which opium is positively contraindicated. First and foremost is chronic interstitial nephritis. I regard the use of morphin in this form of Bright's disease as harmful in the extreme, and the hypodermic injection of morphin in such cases should be positively forbidden. It is this form of disease in which I have known so many cases launched upon a last sleep whence they have never awakened. I do not think it possible to be too emphatic on this subject, and I desire to raise my voice against it in the strongest terms. The beginning of the evil result is a diminution and finally a suppression of urine, followed by coma and death. It is especially in old persons in whom chronic interstitial nephritis is unsuspected in which this accident occurs. Hence too, the importance of examining the urine of old persons before administering opium.

After chronic interstitial nephritis come cases of so-called surgical kidney or suppurating kidney due to stone in the bladder, tuberculosis of the kidney and the like. The danger in these cases depends a good deal on the degree of kidney substance destroyed. It is well known that operation alone in some of these cases becomes the exciting cause of graver changes which terminate in uremia, as seen in the well-known case of the Emperor Napoleon III., while I am confident the use of opium has precipitated many more. Fortunately, the modern practice of surgeons in repudiating almost entirely the use of opium after operations, has served to diminish largely the number of accidents from this cause, while another saving clause exists in the fact that while the kidney is often extensively destroyed, in many cases there remain considerable areas in which the kidney substance is sound. This is in marked contrast to the state of affairs in chronic interstitial nephritis, where the invasion is uniform.

Finally, the more extensive the destruction of the kidney, whatever the form of the disease, the greater the danger from the use of opium. Therefore, chronicity becomes in a general way a measure of the danger risked. I say, in a measure, because the progress in different cases varies so much that duration is not always a measure of the destruction of the kidney. On this account, chronicity has its limitations as a sign of danger when we have not chronic interstitial nephritis. On the other hand, it becomes more important to insist on great caution in the use of opium in every case of renal disease. In chronic cases of the more doubtful kind, the way may be felt by means of very small doses gradually increased, where opium is indicated for any cause.

A corollary following from the last rule brings us to those cases in which the use of opium is least harmful and in many conditions most happy in its influences. These are cases of acute nephritis and of puerperal nephritis, and the condition in which it is often useful is the uremic convulsion in such cases. The use of opium in the treatment of uremic convulsions in acute Bright's disease is intimately associated with the name of Alfred Loomis, and his original position has been

much misrepresented. It was only in acute Bright's disease, as Dr. Loomis himself has told me, that he recommended hypodermic injections of morphin, while others claiming to follow him have advised it for convulsions in all stages. I believe Dr. Loomis' original position is justified and that we may still use with signal advantage this mode of treatment. The only risk lies in cases in which the diagnosis is doubtful, and the treatment should not be applied without careful investigation—indeed, dispensed with except in cases of absolute certainty.

The treatment of puerperal convulsions by the hypodermic injection of morphin is justified on the ground that most of these patients represent cases of acute nephritis. But here even more than in the cases just described, great caution should be used, for not every case of puerperal convulsions is a case of acute Bright's disease, and now and then it happens that death is precipitated because such a case happens to be a chronic one and falls in the category of those in which the use of opium is dangerous.

It will appear from what has been said that diagnosis is the safety gauge by which danger is to be averted. First of all, we should be certain that cases of other disease requiring the use of morphin are not complicated with chronic Bright's disease. Cases in which I have known accident to happen have been simple diarrhea calling for the use of opium and violently painful conditions, such as angina pectoris. In no symptom of Bright's disease itself can opium be of use except in convulsions, and for this symptom only in cases of acute nephritis whether originating from the ordinary causes or pregnancy, and so rarely in chronic parenchymatous nephritis that it may be practically ignored. Finally, under no circumstances in chronic interstitial nephritis should opium be used.

In conclusion, I beg to be understood that I do not repudiate altogether iron and opium in Bright's disease, but desire to limit them to a rational and safe use.

DISCUSSION.

Dr. H. A. WEST of Galveston, Texas—I wish to speak of one point brought out by the writer, that acute Bright's disease is not attended by anemia and therefore that iron is contraindicated in this disease. I believe that many cases of acute Bright's disease are attended by anemia and therefore are much benefited by iron; it is absolutely beneficial when anemia exists.

Another point I wish to make mention of is in regard to the use of opium in the treatment of certain forms of uremic convulsions. My experience has been to find that a hypodermic of morphin is the only means of controlling effectually the convulsions which accompany such diseases as diphtheria. Chloroform, hydrate of chloral, bromids, etc., fail to control severe uremic convulsions, especially of the puerperal kind, but they are controlled by heroic doses of morphin and atropin. It has been my experience to see many such cases. There are cases of uremic convulsions, not of chronic Bright's disease, where lives can be saved by heroic administration of morphin.

Dr. STOCKTON of Buffalo—Dr. Tyson has brought out many points for discussion. In the first place I will express my views as to the use of opium in Bright's disease. I am glad he has stated just what he has. There are instances in which the hypodermic injection of morphin will save lives when no other remedy is available. As to the use of iron I do not altogether agree with him. I think with the gentleman that last spoke, that if anemia is present iron is beneficial. I do not think that Dr. Tyson will deny that statement. Anemia occurs rapidly and should be combated. Another point relates to the amount of the iron to be given to combat the anemia. In my experience, if we depend upon a small amount of iron there is not nearly so much absorbed as there would be if a larger amount was used.

Dr. BROWN of Cincinnati, Ohio—Every particular form of

Bright's disease is one in which there is some danger in using iron and opium.

Dr. VAN HORN of Illinois—I am much pleased with the paper. In puerperal convulsions, I think if the gentlemen will use the lancet the condition will be relieved quickly and surely and they will have no occasion to use morphin or the bromide.

Dr. TYSON—Some of the speakers have not exactly appreciated the position I take. I do not deny that anemia does occur in acute Bright's disease. The point I take is that when anemia occurs early in Bright's disease, it is a secondary symptom. The more urgent symptoms are those which require treatment. Relief should be first directed to the scanty or suppressed urine and to the dropsy. I admit that anemia supervenes rapidly in acute Bright's disease, and here we should use iron, but only after the dangers are gone. The question naturally arises in acute Bright's disease where the acute form ends and the other begins.

In regard to uremic convulsions, I accept the statement that this is a form of convulsion that a hypodermic of morphin will often benefit. The same is true also of the convulsions occurring in parenchymatous nephritis. I admit, too, that after other measures have been used, and there is a necessity of doing something more, then opium may be permitted. But I am certain that convulsions have been precipitated by the use of that drug, especially when it is associated with atropin, as both drugs co-operate to produce suppression of urine. I agree with Dr. Van Horn in regard to the use of the lancet.

Chronic interstitial nephritis happens to be the form of disease in which these two drugs are contraindicated, simply because in this form there is restricted elimination; the danger is from further restriction. Destruction of the cells is more extensive in this form than in parenchymatous nephritis.

THE COURSE AND MANAGEMENT OF COMPLICATING MYOCARDITIS.

Presented to the Section on Practice of Medicine, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY LOUIS FAUGÈRES BISHOP, A.M., M.D.
NEW YORK.

In the course of the practice of medicine, as diseases and conditions are unconsciously classified, ideas gradually develop themselves that are not easy to formulate into the language of exact scientific observation. One of these impressions has been that in the debility following severe diseases, there is some more definite underlying condition than is usually formulated. The explanation alone of an exhausted and deteriorated nervous system is not sufficient. The attention is drawn to the heart muscle, and clinical observation, confirmed by the pathologic observations of others, has led to the belief that complicating myocarditis is an important factor in the course and progress of many conditions. The signs of disease of the heart muscle should therefore be studied with care. In acute diseases and wasting diseases, whatever may be their nature, there come times when it seems evident that the heart has participated in the debility and degeneration that is visible in the other tissues of the body. So we find in the milder cases a condition of simple weakness of contraction, in the more severe, signs more suggestive of myocarditis, namely irregularity in force and rhythm. When after an acute disease, or in the course of a chronic affection these signs are noted it becomes important to interpret their meaning and study their indications.

Our conception of the condition under consideration is an inflammatory state of the myocardium following acute diseases, occurring in the course of chronic wasting disease, or beginning as an extension of inflammation from an endocarditis, or a pericarditis. It is not proposed to consider conditions secondary to diseases of the coronary arteries or excessive hypertrophy. Our subject does not demand an extended reference to pathology. A form may occa-

sionally originate in an acute interstitial myocarditis, but more frequently it is a parenchymatous degeneration. Dr. Osler remarks that it is probably the effect of a toxic agent, and that there is no definite relation between it and high temperature.

Every one is familiar with the appearance of the heart muscle in a patient dead from an acute prolonged illness. It differs in appearance from the heart of a person who has been killed by accident while in good health. In the former the muscle is pale and grayish looking, while in the latter it is firm and of healthy color. Probably in many diseases there is this low grade of inflammation that is not more than a slight degeneration.

It is not easy to be sure that a true myocarditis underlies any particular symptoms, but there are some that are of more importance than others. These are relative feebleness of impulse, especially under the stimulus of slight exercise, disturbances of rhythm and undue rapidity, following the resumption of standing position by a person most of the time recumbent. Such signs with dyspnea and prostration complete the picture of complicating myocarditis. Cardiac murmurs may, or may not, be present.

It has seemed to me that arrhythmia in patients who had not previously shown this symptom is specially suggestive.

Dr. Jacobi says in his book on "Therapeutics of Infancy and Childhood," "We are beginning to become more and more aware of the frequency of affections of the heart muscle. Myocarditis in a chronic, sub-acute and acute form is of very frequent occurrence. In or after every case of typhoid fever, scarlatina, diphtheria or smallpox, we must prepare to be overtaken by some cardiac disease, either interstitial myocarditis or parenchymatous degeneration. Rest in bed or on a lounge (the former is better), will act as a preventive. It ought to be continued for weeks in almost every case. Like paralysis; subsequent upon infectious diseases, which develop after weeks, heart disease may occur from the same cause, partly as a subsequence of actual primary alterations, partly from nervous exhaustion. So long as the pulse becomes more rapid on exertion, or on getting out of bed, absolute rest is the best remedy and safeguard. In these cases, it is not always possible to distinguish between functional debility and actual disease."

Dr. Jacobi again remarks in the course of his book, "Though myocarditis, both acute and chronic, is by no means so frequent in the child as in the adult, it is nevertheless not infrequent. It is indeed remarkable to observe how often it is not diagnosed, or how little its occurrence is appreciated."

Myocarditis must always be feared when there are signs of impaired heart action, especially feebleness and irregularity of force and rhythm, that the underlying condition is disease of the heart muscle. These cases are too often carelessly diagnosed as general debility, or as instances of disturbed cardiac innervation. It is important that the real condition should be recognized because the treatment may otherwise be prejudicial. Stimulants directed to the heart itself are certainly philosophically contra-indicated. We might whip a lazy horse, or we might improve the behavior of a nervous horse by discipline, but a sick horse should always be rested and fed. So in the case of a heart that is feeble and behaving badly on account of myocarditis following a severe disease, muscle stimulants should be avoided.

Especially is the care of the heart muscle important in those cases of acute infectious diseases in which a valve lesion has unfortunately been developed by complicating endocarditis. In severe endocarditis myocarditis also probably exists, so that there is a double call upon the forces, as the heart must not only regain its normal power, but also learn to do greater work to make up for the lesion in the valve. Particularly is it important for these patients to follow a long and strict regimen, avoiding indiscretions of diet, sudden exertions and dissipation of all kinds.

The treatment of degeneration of the heart fiber when that is far advanced is a difficult problem. Indeed, when on account of the evidence of well-marked symptoms we can say definitely that such a process is going on, it is often too late to accomplish a great deal. The hopeful cases, and those which it is especially desired to call to the attention at this time, are those of complicating myocarditis, met with as an accompaniment of acute diseases, and to urge the care of this condition during the course of the disease, and during convalescence, so that ultimately the heart may regain its true tone. Instances of weak heart following acute disease are not wanting in any one's experience.

One of the dangers to the person suffering from myocarditis is the possible result of sudden over-exertion, causing an acute dilatation of the heart from which recovery is not easy. The proper regulation of the muscular activity of the patient is therefore of the utmost importance. Exercise undertaken to improve the general bodily nutrition, and that of the heart muscle in particular, should be light, slow and systematic. Next to exercise comes diet. Food should be concentrated so that the nourishment is administered in small volume, leading to an easy performance of the functions of the stomach without the tendency to distension, such as may mechanically embarrass the function of the heart and lungs. With the principle of small volume of food, much latitude as to variety may be permitted. The use of alcohol, without its abuse, in cardiac cases is very difficult. Probably a small quantity with meals is not harmful. But any excess is always followed by injury. The use of tea and coffee is a good deal a matter of experience with particular patients, but the extreme frequency of cardiac symptoms produced in persons with normal hearts by tea, and the fact that both tea and coffee are recognized as cardiac stimulants, should make us take the stand with our patients that these being cardiac drugs should be controlled by their physician. The use of tobacco is better discontinued. Often enough patients with defective hearts recognize themselves the discomfort, or rather the lack of satisfaction, in the use of tobacco and spontaneously abandon it. But others have become habituated to its use so that the effects are not obvious, still these can be taught that the effect of tobacco will finally prejudice their future.

As the heart can not be treated directly, we must rely much upon the possible auxiliaries to the cardiac propulsive effort. It is unlikely that the heart alone, even in health, would be able under every circumstance to carry on the circulation. To imitate in inanimate material, a system of tubes and valves, such as the circulatory system of the human body, would be impossible, but if such a structure were possible it would not operate. The slightest defect would cause serious interruption of the current. In

the circulation in the animal body there is provision made for enlargement of vessels here and contraction there so that the size of the tubes are always as required for the blood current. A demand for a larger amount of blood determines an enlarged blood vessel. Of course the heart supplies the main impulse to the blood, but the resiliency of the blood vessels, and their contraction and expansion under many varying conditions, must be important factors in the circulation. Taking advantage of this in cases of insufficient systole, much can be done to assist the circulation. This is notably accomplished by judicious exercise, stimulating baths and massage. Nor is the benefit of pleasant diversion in improving the nervous tone to be neglected.

Thus we see that in the course of many acute infectious diseases the heart muscle becomes affected by changes of an inflammatory or degenerative nature. Usually this is a part of a general condition affecting all the muscles of the body. But the heart muscle is of so much more importance, and the course and progress of the myocarditis bears such a vital relation to the well being of the patient it names the condition. The picture presented by the convalescent from an acute disease, who has escaped with a healthy heart, is very different from the one who has suffered from degeneration of the heart muscle. The former regains health and strength rapidly; the pulse becomes strong, the color returns, and the patient is soon in good health again. The patient with complicating myocarditis lingers along in a condition of semi-invalidism. The disease from which he originally suffered has entirely disappeared. There is apparently no reason that he should not recover strength and health, but the heart for a long time remains weak, unless its state be recognized and particular measures be employed to restore its integrity. This chronic complicating myocarditis explains symptoms so often witnessed after diphtheria, grippe, scarlet fever, and other diseases characterized by a violent infection.

THE CAUSES OF THE INCONSTANCY OF MITRAL REGURGITANT MURMURS.

Presented to the Section on Practice of Medicine at the Forty-ninth Annual Meeting of the American Medical Association held at Denver, Colo., June 7-10, 1898.

BY J. N. HALL, M.D.

DENVER.

Inconstancy is much more frequently a characteristic of regurgitant murmurs at the auriculo-ventricular orifices of the heart than of any other cardiac murmurs. We propose to study the reasons for this inconstancy, particularly as affecting the mitral valve, although much that we say applies equally well to the tricuspid. We shall first look briefly into the character and mode of production of the other murmurs. At the arterial orifices we may have direct murmurs from anemia, or infinitely less often, from obstruction in some form; and regurgitant ones from *a*, damage to the leaflets of the valves, or *b*, stretching of the ring supporting them. All of these are practically constant excepting the direct ones of anemic origin, which disappear under the use of iron in many cases.

Presystolic murmurs originate from narrowing of the auriculo-ventricular orifices, and are, practically, constant, excepting that weakening of the auricular wall may lower the force of the blood current to such

an extent as to render the vibrations inaudible. This phenomenon probably occurs in most cases of this nature after interruption of compensation. Leaving out of consideration the anemic murmurs, the murmurs we have just considered depend commonly upon conditions of the valve segments or the orifices brought about by endocarditis or atheromatous processes, and not subject to rapid changes either from medication or changes in blood pressure. As regards regurgitant murmurs at the auriculo-ventricular orifices the matter stands very differently, chiefly owing to the different mechanical conditions entering into the problem. Mitral systolic murmurs are frequently hemic in character, and these are subject to frequent variation from changes in the condition of the blood, as are hemic murmurs elsewhere. It is especially common to see them disappear under the use of iron. I believe that very soft, slightly musical systolic murmurs at the apex in children are most frequently hemic in nature. We should note that it is probable that certain apical murmurs in severe anemia are really regurgitant in nature, and yet disappear under treatment, for the weakness of the myocardium from insufficient nourishment in such cases may give rise to temporary insufficiency, the weakened papillary muscle failing to draw the valve-segments accurately together. We should mention here those murmurs heard in certain phases of respiration only, and yet synchronous with the apex-beat, only to dismiss them, since they do not come properly within the scope of this paper, not originating within the heart.

The fact that the heart is hinged upon the great vessels at its base, and therefore may be more easily displaced from the chest wall at its apical portion than at its basic by changes in posture, intervention of the lung, effusions or tumors, constitutes a further reason for the inconstancy of certain mitral murmurs because the source of the abnormal sound is easily pushed back from the chest wall by the causes mentioned. Although the vibrations still exist, they may not reach the chest wall under these circumstances.

The transmissibility of a murmur is so obviously dependent upon the force of the blood current that a change in its area of transmission is to be expected with change in power of the heart muscle. Cammann formerly stated that the existence of mitral leakage was established only by hearing the systolic murmurs transmitted to the back. This is obviously incorrect, for cases are common in which, during established compensation, the murmur is to be heard in the back, while it disappears with failure of this process, even to reappear after a temporary restoration of heart-power. Although the disappearance of the murmur from lessening of the force of the blood current is perhaps more strikingly seen in connection with mitral stenosis than with mitral leakage, the basic murmurs are less liable to such change than either of these. An apical systolic murmur occasionally replaces suddenly the presystolic murmurs of stenosis, owing to rupture of the stenotic valve. We need only mention this rare phenomenon.

Above all the causes thus far mentioned, however, is the peculiar structure of the auriculo-ventricular orifices, to which we must look for the explanation of the inconstancy of many systolic murmurs. The relatively large size of the ring, its comparatively easy dilatability, the presence of papillary muscles assisting in the closure of the orifice, and above all the

attachment of these papillary muscles to the easily dilatable ventricular walls, offer abundant opportunities for leakage at the orifice and the consequent development of abnormal sounds. We should not, therefore, be surprised at the comparative frequency of occurrence of the murmurs in question. Although the valve-segments be perfect, we may readily see that leakage may occur, *a*, from dilatation of the ring to such an extent that the valves can no longer cover the opening; *b*, from stretching of the papillary muscles or loss of their contractile power, as from degeneration of their muscular tissue, so that the valve-segments are pushed too far into the auricle to meet accurately; *c*, from contraction of these muscles and of their chordæ tendineæ from endocarditic changes, so that the valves are unable to meet together; *d*, from a retraction into the ventricle of the leaflets of the valve from dilatation of the cavity, this serving to increase the distance between the point of origin of the muscle and the normal meeting place of the leaflets of the valve. Thus, although ring, leaflets and papillary muscles be normal, leakage occurs.

As all the conditions herein specified are subject to change, in some cases, as for example the last one quoted, to very rapid change, we need not be surprised at the great variations to be found in the physical signs in such cases. Drugs have vastly more influence in producing such changes than, for instance, at the aortic orifice, where the mechanical problem of closing the opening is much simpler. Thus an improvement in the tonicity and contractile power of the myocardium from the administration of digitalis may cause a leakage to disappear, as I have repeatedly observed, by its effect in abolishing the dilatation of the left ventricle, thus bringing the walls of the cavity, where are attached the papillary muscles, near enough to the normal position to permit of efficient closure of the valve segments.

Roy and Adami believe that strophanthus acts particularly upon the papillary muscle. In leakage due to fault of this structure, an increase in the contractile power from the drug mentioned may possibly cause the murmur to disappear. The yielding of the ring is greater under conditions of increased blood pressure, but a murmur present from this cause alone is likely to be fairly constant because of the lack of elasticity in the structures composing the ring, and to consequent inability to regain its previous condition.

We know that the advance of a stenotic process at the mitral orifice lessens the gravity of a concomitant regurgitation by diminishing the size of the orifice. It is probably possible that a regurgitant murmur may disappear for a time by such a process. The most constant murmurs are probably those originating from insufficiency due to endocarditic defect in the leaflets, or to shortening of the chordæ tendineæ by the same process. Such murmurs are probably constant excepting as they fail from great lowering of the blood tension, although they may fail of transmission to the surface because of the intervention of effusions, or otherwise.

Chloroform Treatment of Yellow Fever.—The National Academy of Medicine at Rio Janeiro is much interested in a new treatment for yellow fever proposed by Dr. Erico Coelho, which he has used with great success in his private and hospital practice. It consists merely in the inhalation of chloroform for hours during the early stages of the disease.—*O Brazil Médico*, May 8.

TUBERCULOSIS AND ITS TREATMENT BY THE LATER METHODS.

SUBJECT ILLUSTRATED BY TWELVE CLINICAL CASES.

Presented to the Section on Practice of Medicine at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY A. G. DEARDOFF, M.D.

SAN FRANCISCO, CAL.

I wish to add my experience in the use of one of the later remedies in arresting, and in the earlier stages, of curing tuberculosis. There are many new remedies used in tubercular troubles which prolong life and frequently cure that only a few years ago were unknown in the treatment of this dread disease which, as all medical men know, causes more death and distress in the human family than any other one trouble. I condemn none of these new remedies, but to the best of my ability, have investigated several, and the one that appeals to my better judgment is Dr. Paul Paquin's Anti-tubercular Serum and Anti-streptococcus Serum. The use of this serum in my own practice has convinced me that it is good. Revolutions come in medicine as in other things. A remedy will have a wide notoriety for a time by advertising, etc., but unless it has merit, it is soon thrown aside. To see a remedy grow continually in favor as this serum has, is a good proof of its reliability.

Jenner, many years ago, by his investigations, gave to mankind a virus that stopped the ravages of smallpox, and the terror of this disease is gone and it is almost totally eradicated from the earth and kept in absolute subjection.

Diphtheria is now controlled, and many cases cured by the anti-toxin serum. Many cities now have depots with this serum under the management of their boards of health. It undoubtedly has saved many lives, and physicians feel that they have a reliable remedy for this great enemy of childhood.

On the same line of reasoning we have the anti-tubercular serum, made from the blood of the horse, for tubercular troubles. Instead of this serum losing ground as many other treatments have done, it seems to be gradually gaining in popularity. By the use of the microscope the investigations of so many along the line of tubercular diseases, it is to be hoped that before long we will have on this same line of reasoning a remedy we can absolutely rely on, as we do now on the smallpox virus and the antitoxin for diphtheria. I have reason to believe such a time is approaching, and this would relieve the human family of another of its destroyers and greatest enemies.

While the cases I report are not numerous, my experience with these and others proves to me that there is something in this treatment well worth investigating. I must insist, however, that if a physician uses this serum on a patient, it shall be used regularly and continuously and be under the supervision of the physician. For using it a week or a month, then tiring of it, will simply bring reproach on the remedy and no permanent good to the patient. Intestinal antiseptics such as gnaiacol, sulpho-carb. zinc, creosote, sat. sol. sod. borate, or any other good intestinal antiseptic should be used internally. Borolyptol, lyserin and other antiseptics sprayed into the mouth and fauces as the physician thinks necessary. Good food, fresh air, all these favorable conditions must be recognized and used in connection with the serum. Some will say, tuberculosis will improve under this

treatment without the serum; perhaps improve, but not cure.

When a case comes to us with night sweats, hectic fever, temperature 101 to 103 evenings, pulse 100 to 120, patient fast losing flesh, no appetite, profuse expectoration or a dry, irritable cough, and on auscultation and percussion undoubted signs of tubercular disease, and all these symptoms confirmed by the microscope, we know what these conditions mean.

When we begin with this serum and in one week the night sweats are lessened or entirely gone, better sleep, appetite improving, and in one or two months a gain of five, eight or fifteen pounds, we then *know* some great change has been wrought in the system. I have had many such results in relieving cases. The microscope was used in every case by a competent bacteriologist to confirm the diagnosis made by the physical examination.

Case 1.—First stage.—In March, 1897, I began treating young C., aged 11 years. His mother had died of phthisis one month before. He had been ill for three months. Mornings, had profuse expectoration full of tubercular germs, as shown by the microscope. Hectic flush, loss of appetite, and fever at night. I treated him forty days, and had the satisfaction of seeing him restored to health, with a gain of eight pounds in weight and a growth of almost an inch in height in four months. A complete cessation of cough, and on auscultation and percussion, no abnormal sounds could be heard. Have examined him every month since, and he seems perfectly well. Nearly a year has passed and no return of symptoms. No medicine was used in this case except an occasional dose of mild hydrarg. chlorid as a hepatic stimulant.

Case 2.—First stage.—Mrs. P., aged about 40, in May of 1897 applied to me for relief from a severe cough with slight expectoration. Tubercular deposit in apex of right lung; microscope confirmed diagnosis, but few bacilli observed. I treated her for three months daily with the serum, effecting a complete cessation of cough. Muscular weariness and cachexia of tuberculosis gone. She rested one month from treatment, then I gave her another month's treatment of the serum. I used no medicine in this case but the serum, excepting an occasional dose of mild hydrarg chlorid. Up to date she is well and carrying on her business (typewriting in a large office where there are many people and very bad air). Her mother died of tuberculosis.

Case 3.—First stage.—Mrs. H., age 29 years, began treatment in June, 1897. Mother and father died of tuberculosis. Had been sick six months. Appetite poor and tubercular cachexia marked. Was a very large woman, five feet, eleven and one-half inches in height. Normal weight 200 pounds. When she began treatment weighed 160 pounds. Microscope confirmed diagnosis of tubercular disease. A deposit was located in apex of both lungs. I treated her daily for one month. A change for the better could be noticed in two weeks. The second month I treated her every other day. I then sent her to San Diego for two months, expecting her to return for two months' more treatment. She returned, but was so well that I considered it unnecessary to pursue treatment further. Her weight after four months was 200 pounds, cough gone, lungs cleared up, and on auscultation and percussion no abnormal sounds could be heard. A peculiar circumstance in connection with this case was a complete cessation of a profuse uterine catarrh, which she had had for several years.

Case 4.—First stage.—Miss D., aged 26 years, applied for examination in December, 1897. For six months had felt tired, languid, and could not endure her clerical work, so had to give up her position. Middle lobe of right lung showed a small tubercular deposit. Expectoration very scant, appetite poor. Tuberculosis in family; aunts and uncles died with it; and it is supposed she contracted it from them, as they died at her home with tuberculosis several years before. A brother, of whom I will speak later on, has the disease. A peculiar feature of this case was a dry, scaly dandruff condition of the skin over the shoulders and back. It made no difference what care she took of herself in bathing and applications, this condition persisted. After using the serum treatment for two months the skin became healthy and has continued so. All symptoms of tuberculosis gone and she is now in good health.

Case 1.—Second stage.—Mrs. G., aged 37 years, applied to me for treatment in December, 1896. Mother and one sister died of tuberculosis. Was sick for six months before applying

for treatment. Normal weight 125 pounds. When beginning treatment weighed 115 pounds. Hectic fever, night sweats, loss of appetite, and a burning sensation beneath left clavicle. The diseased spot was in the upper lobe of the left lung. I found one small cavity. Moderate expectoration of mornings. I treated her three months daily with serum and she improved rapidly. At the end of four months had gained in weight to 135 pounds, more than she had ever weighed in her life. I used but little medicine, only correctives. At the end of this time cough had disappeared. This case used the serum per rectum two months after I stopped using it with the hypodermic. I have examined her in the last three months and find her perfectly well.

Case 2.—Second stage.—Mr. W., age 24 years, a young German. Father and brother died of tuberculosis. He had been ill about six months. Frequent cough, profuse expectoration, sleepless nights, loss of appetite, night sweats and hectic fever, pulse 95 to 110, temperature from 1 to 2 degrees above normal in evenings, weight 145 pounds. Normal weight 170 pounds. Tubercular deposit located in upper lobe of right lung. Small cavity. Microscope confirmed diagnosis. Was treated two months daily with serum. After two weeks temperature and pulse normal. Gained fifteen pounds during the first three weeks. Expectoration gradually declined until at the end of six weeks it had almost ceased. No one could have changed faster from a fast decline back to health than did this man. He left the city after the second month's treatment feeling as well as he ever did, and had regained his normal weight.

Case 3.—Second stage.—I class this patient in the second stage, having been affected for about five years with a general systemic tubercular poison, and for eight months marked throat trouble, indicating laryngeal phthisis. Mr. D., age 24 years, brother of Miss D. of whom I have already spoken, applied to me for treatment in November, 1897. Weight 130 pounds. For several years had been feeling badly. Had no cough, but had catarrhal secretions from fauces which caused an occasional clearing of the throat. A depressed feeling of lassitude, skin dry and scaly, hair poorly nourished, and marked tubercular cachexia. At times would have fever for one, two and three weeks, then better again. This fever was supposed to be malaria. Had taken most all kinds of tonics, had been to springs, and was away from home every summer to the mountains. Examination of lungs proved negative. The secretion from the throat being examined by the microscope showed large quantities of tubercular bacilli. His whole system was perfectly saturated with tuberculosis. I treated him daily for three months and he improved rapidly. Tubercular cachexia cleared up and skin changed to a red glow of health. I also used an antiseptic spray for the throat several times a day. Made applications of argent. nit., tincture of iodine and glycerin in the throat. This patient is now using the serum at home every other day under my direction. I see him weekly and he is doing well.

Case 1.—Third stage.—Mr. S., aged 29 years, applied to me for examination in September, 1895. He was taken ill in June of 1895 with what he considered at that time malaria. Had a cough several months previous. He was a cigarette smoker, and a "speedy" young man in every sense of the word. His mother had died of tuberculosis several years before. His lungs broke down rapidly, and when he applied to me for treatment in September, he was in the third stage of tuberculosis. One quite large cavity in the upper lobe of right lung. Infiltrated spots throughout different portions of the lungs. A terrific cough and profuse expectoration. Had had three hemorrhages before coming to me. Three to five night sweats every night. He returned home taking tonics with him. He returned to me about the first of November, 1895, very much emaciated with loss of appetite and profuse night sweats. I placed him under the care of a professional nurse for one month; with all these symptoms three or four months at the longest, under ordinary treatment, would surely have been as long as he could have lived. I put him on tonics, antiseptic sprays for lungs, and at once began injections of anti-tubercular serum. I had not used it five days before the night sweats had almost ceased; slept better; appetite better; and after a few weeks the infiltrated spots in the lungs were fast clearing up. His fever ran lower, pulse lower, and he was fast improving. When he first applied to me for treatment his temperature was 103 evenings, pulse 125 to 130; and at the end of the month he was so much better that he dispensed with the nurse and began going out to theaters and various places of amusement, entirely against my wishes; still he took his serum regularly, and both of us were very sanguine of permanent results. He began his excesses in the old way of "wine and women," but still improved. He was very well when he left me after four months treatment. He was able to attend to his work;

very little cough, and had no hemorrhage while I treated him. After he went home he continued these excesses. About two months of this kind of life, and the neglect of the serum, he suddenly had a severe hemorrhage, then gradually went down. He went to the mountains. The serum treatment was entirely neglected, and he lived almost a year after this hemorrhage. This man was on the road to recovery and we might say deliberately suicided. The wonderful change wrought in him by the serum gave me to understand that I had access to a remedy that I could hold out some hope to the tuberculous patient; for it had undoubtedly turned a patient most dead with tuberculosis back to health and normal strength, and by his own recklessness he had fallen again to its ravages. This was the first case I treated with anti-tubercular serum.

Case 2.—Third stage.—In the spring of 1896, Mrs. B., of Chicago, aged 42 years, applied to me for treatment for a continued cough. She informed me that she had had trouble for three or four years, and her physician had sent her to California, for he did not think she would live long in Chicago climate. Mother and father both died with tuberculosis. Microscope showed large quantities of tubercular bacilli. She had two hemorrhages, one before, and one soon after I began her treatment. Small cavity in central part of upper lobe of right lung. I treated her six weeks. She then went to St. Louis and continued the treatment for three or four months. She spent the winter of '96 and '97 among the pines of North Carolina and returned to California in the fall of '97. She was perfectly well and all expectoration had ceased. In this case I combined tonics and cod-liver oil with the serum treatment.

Case 3.—Third stage.—Mrs. C., aged 36 years, in November, 1896, applied to me for treatment; bad cough and had not been well for nearly a year. Had a severe hemorrhage just before beginning the treatment. Was bedfast. Pulse 120 to 130, temperature 103 every afternoon. No night sweats, but loss of appetite and very much emaciated. Mother, two sisters and brother died of tuberculosis. Her normal weight was 125 pounds. Weight when she began treatment 105 pounds. I had trouble the first two weeks in giving her the serum. It had quite a severe reaction on her but in three weeks she began to improve. The fifth and sixth weeks she gained one half pound each day. Then she slowly gained until her weight was 123 pounds. I treated her until February 1897, when she returned home and used the serum per rectum, but it did not have as good effect on her as by hypodermic, causing her severe nervousness and prostration. In May 1897 she returned to me and used it one month, and she improved rapidly. Again returning to her home, used the serum hypodermically. She returned to the city and I treated her during August and September of 1897. On account of some pus in the sputum at this time I used the anti-streptococcus serum for a few weeks, which had a decided effect on clearing up the expectoration. She is using the serum now, changing occasionally to antistreptococcus serum. She is in good health, but not entirely well. Expectoration is almost gone. This case would have done better had she been under my observation all the time, but on account of her family it was impossible for her to remain with me continuously. In this case I used proto-nuclein, cod-liver oil, and strychn., at times, as a nerve stimulant. She is now using carnegene, the red and white marrow of beef, instead of cod-liver oil, and is gradually improving. This case is still under my treatment with the serum. The microscope was used about eight months after beginning treatment and the slides compared, showed a large decrease in the tubercular bacilli.

Case 4.—Third stage.—Mrs. L., aged 57 years, applied to me for treatment in the fall of 1897. Family history shows tuberculosis. Father, mother, and all her brothers and sisters died of tuberculosis. Had been affected for twenty-five years. Microscope showed quantities of tubercular bacilli. Percussion and auscultation showed right lung almost gone. Cavities in left lung, profuse expectoration, occasional night sweats, bad dyspepsia, temperature ranging from 99½ to 102 evenings, pulse averaged about 80, tuberculous ulceration of bowels causing more or less diarrhea. For some years was obliged to eliminate many things from her diet, such as tomatoes, lemons, peaches, and all fruits of an acid nature. I used a mixed treatment in her case of anti-tubercular serum and anti-streptococcus, it lessened her cough. In two months her appetite was improved, she could eat anything she desired and no bad results from it. After three months treatment she went away from the city and was using the serum per rectum. I have not heard from her since she left San Francisco. I could not expect any permanent improvement in such a case as this, though she was much relieved. I gave her intestinal antiseptics and proto-nuclein, and also iodoform capsules internally in connection with the serum.

Case 5.—Third stage.—December 2, 1897, I was called to

see Miss B., age 26 years. She had been treated by tonics, creosote and the same old treatment with which we are all familiar. She had been ill for six months. This patient was almost dead. The microscope showed tubercular bacilli in abundance. Her pulse 150, temperature $104\frac{1}{2}$, examination of lungs showed upper lobes of both badly affected from apex down. Severe night sweats, and almost an absence of digestion with such ferment in her bowels that she suffered severely with them. Her whole system was saturated with tuberculosis. So bad was this case that I thought she would die before two weeks, and considered it useless to treat the case as others had given her up. On the earnest solicitations of her relatives I began treating her; using anti-tubercular serum, and at the end of four days had the amount of serum per dose up to twenty drops, which is double the amount for that time in ordinary cases. She then began to feel better. I placed her on intestinal antiseptics. Her digestion improved and the night sweats ceased entirely. At the end of the first month she was able to take a ride every day, if the weather would permit. During the second month she had a relapse on account of a small abscess forming and breaking in the right lung. She again improved. At the end of three months she took the measles; this was serious for her, but she came through all right. At the end of four months she went to the country, and is using the antitubercular serum per rectum. She is still living and feeling well, but not improving. Her pulse came down to 80 and 90 from 130 to 150, temperature normal of mornings, and 100 to $100\frac{1}{2}$ evenings, and at times normal of evenings. Digestion good, appetite good. I had a decided effect in this case in assisting the serum treatment by the use of sat. sol. of borat. sod. one ounce each day per rectum, a tablespoonful three times a day internally. I think this a fine addition in the treatment of tubercular diseases.

I have selected these twelve cases for report, as they are about average cases with me. To recapitulate:

Five cases—third stage.—One dead; one benefited some; one greatly benefited; one well; one living six months after being given up to die at any time.

Three cases—second stage.—One greatly improved; one well over one year; one improving fast.

Four cases—first stage.—Four well.

I advise tonics, cod-liver oil, antiseptics sprayed in the throat and lungs of boro-lyptol, listerin, etc. I advise two or three times a week an enema or normal solution of sod. chlorid per rectum and flush the colon. This acts as a disinfectant, and the absorption of a portion of this solution in the circulation is very beneficial to the patient. Then I wish to impress the good of using sat. solut. of borat. sod., tablespoonful internally three times a day, and about an ounce injected each day in the rectum. When pus exists in the sputum, I advise the use of anti-streptococcus, alternating with the anti-tubercular serum, and the effect is at once marked.

My success has been so great in many other cases and I feel that I can almost insure a case in the first, or incipient stage, where the cavities are small, that many will improve, and at times recover even in the second stage, and occasionally in the third stage.

MODERN METHODS IN THE TREATMENT OF TUBERCULOSIS.

Presented to the Section on Practice of Medicine at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY WILLIAM F. WAUGH, A.M., M.D.

PROFESSOR OF PRACTICE OF MEDICINE, ETC., ILLINOIS MEDICAL COLLEGE.

If we believe that for every ill that affects humanity there is somewhere a remedy, it would seem that even through the operation of blind chance there was a fair opportunity for lighting upon the means of curing tuberculosis. For in all parts of the medical world there is put into practice a most miscellaneous assortment of experiments. The power of suggestion is being demonstrated by the claims made in behalf

of nearly all these essays. The need is so terrible, the boon to humanity would be so enormous, that one must look with kindly sympathy upon the man who desires to succeed.

The fact that success in this matter means so much to humanity demands from us most careful scrutiny that no really valuable idea shall be lost on the most critical examination, that no delusion shall be permitted to prevail. Should my remarks, therefore assume somewhat the shape of criticism, it is with no unsympathetic or pessimistic spirit, but with the earnest desire to favor the truth.

First, we will consider the climatological aspect of the question. When we inhale the pure breezes of Colorado we do not wonder at the enthusiasm that prevails among the residents as to its salubrity. We recognize at once that this is founded upon reason, not upon commercial scheming. We have sent our patients to the Denver region for years, and can readily recall notable instances of its restoration or even curative effects. But that all cases are not thus benefited is sadly attested by the monuments in yonder populous city of the dead. We trust that the physicians of Denver, who have such exceptional opportunities for the study of the question, will give us clean and definite instructions as to what cases should be sent here, and where to send the others.

At present we have some valuable but scanty data upon which to base our advice. Incipient cases do well here, as they do in most places: the best results are obtained in these instances in which the diagnosis is inferential rather than positive. But hemorrhagic cases ascend to this altitude with peril. They fare badly here as well as at the seashore; so that their destination is problematic. Beside the conditions of the case, there lies behind this a consideration as to the personality of each patient. The effects of climate are not now believed to reside in the power of any atmosphere to starve or to poison the microorganisms. That climate is best for each person, that most conduces to his physical health, that allows him to live the most wholesome life as an animal, usually, in the open air, with sunshine, and free ventilation.

Broadly speaking, mankind is divisible into two classes. Types of both may be found in the same family. If one feels strong and vigorous in the pure, cool thin air of the hills, to the hills he should go; but if he feels bad here, and experiences a sense of comfort, of exhilaration, of renewed vitality when he smells the damp air of the salt meadows, he will there have the best chance for cure. Beyond this, and the injunction to keep as far as possible from other cases of tuberculosis, there is little of certainty in the choice of a climate. As to the effects of any atmosphere upon cases of tubercular, streptococcus, staphylococcus and mixed infection, upon primary microbial affections and these engrafted upon previous inflammatory processes, we have as yet but a feeble light. The hope of securing more has brought many of us to Denver.

Of the various forms of serum therapy, I shall say but little, as the program is filled with numerous papers by those who are better qualified to speak. Be they successes or failures each marks an approximation to the truth, if it be but by clearing the way for further experiment. They are commendable in that they are based upon a study of the phenomena of the disease and of the conditions noted in the biology of the

micro-organisms present. Surely if success be obtainable, it is in this direction.

In this connection I will present some facts worth considering. Tuberculosis is separated from the large majority of microbic affections in that it is not self-limited or self-protective. Tuberculosis is also distinguished from the majority of such affections in that we do not find leucocytosis attending it. Can we correlate these two facts, and infer that the failure of self-immunization is due to the fact that nature has here failed to combat this disease by a multiplication of her defenders, the leucocytes? If, so, we may find value in that singular discovery of Vaughan, that nucleic acid increases the number and activity of the white blood corpuscles. This hypothesis, pregnant with possibilities that may change the science of therapeutics and vitally modify the history of the human race, is all the more worthy of commendation in that it brings us back to the truest basis of therapy, the study of the physiologic conditions aberrant in disease and utilizable in its treatment. The finality of therapeutics must be the comprehension, restoration and maintenance of a normal physiologic state.

But vastly important as are the germicidal elements, and the value of climate as a means of reinforcing the vitality to the point of rendering it victorious, they are by no means our only weapons. The armamentaria with which we relieve the various symptoms of tuberculosis require no mention on my part; but I wish to speak of two agents that have served me well. Many years ago I heard Samuel H. Dickson say that when we learn to control the digestive disorders of consumption we would cure that disease. I need not more than refer to the difficulty of feeding these patients, the anorexia, dyspepsia, constipation and diarrhea, malassimilation, etc., marking their history. But all these disappear under the use of calcium sulfocarbolate, and with them from one to three degrees of the fever, and in all, from 30 to 60 per cent. of the sum total of the symptoms and phenomena is removed by this single expedient. These results have followed so uniformly that I feel warranted in suggesting a trial of this salt. I have given it daily in doses of 2 and 6 grains for nearly two years without any discernible objectionable effects.

The other agent is iodoform. In some consumptives there appears to be a tolerance of this drug, as they have taken from 10 to 20 grains daily for months without any symptom of iodism, while this unpleasant condition has followed the use of four grains daily in non-tuberculous individuals. Whether its effects be germicidal, absorbent or simply those of a pulmonary and analgesic, or of all three combined, the use of this remedy has given me better results than any other pulmonary germicide.

THE PSYCHOLOGY OF HABITUAL CONSTIPATION.

Presented to the Section on the Practice of Medicine at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY ALBERT H. BURK, Ph.B., M.D.

ADJUNCT PROFESSOR OF PRACTICE OF MEDICINE COLLEGE OF PHYSICIANS AND SURGEONS, ATTENDING PHYSICIAN PROVIDENT HOSPITAL. CHICAGO, ILL.

Among the great phenomena of nature one of the most interesting is that of the rhythmic action of her forces in obedience to ever constant laws. The cycle of darkness and light that measures a day; of recurring

seasons that calendar a year; of ocean's tidal ebb and flow that mark her throbbing pulse: all these are but so many demonstrations of a universal law of rhythm. In our bodies similar laws of periodicity are essential to organic health or even to life itself. Restful sleep must follow wakeful toil in just proportion and at proper intervals. Respiration and circulation are dependent upon ever constant, regulated muscular impulses. The processes of digestion, assimilation and excretion obey this same law of rhythm. So long as these periodic forces are undisturbed in their rhythm by careless or vicious habits of the individual, or by accidental and pathologic changes beyond his control, healthy, organic functions are assured.

Mental control of rhythmic functions.—The control of these rhythmic forces is for the most part, outside of and beyond our conscious mental appreciation. They act with automatic precision whether we wake or sleep, little influenced by our wills, our desires or our reasoning faculties. They are said to be controlled by the great sympathetic nervous system which connects the various organs of the body in their functions, with ganglionic and cerebro-spinal centers. This is not true in a literal sense; for this wonderful system is itself only a mechanism; an intricate co-ordination of communicating lines, sensitized for the transmission of impressions to and orders from a central governing intelligence. Whether we accept the theory of a dual mind or not, we are forced to the conclusion that this marvelous labyrinth of communicating sympathetic nerves and the organs to which they are distributed, and hence the functions of these organs themselves are dominated by a never sleeping, ever acting intelligent entity.

Since we know these functioning organs and their special nervous systems act for the most part independently of our objection primary consciousness and volition, we are impelled to the belief that they are controlled by a sub-conscious, instinctive faculty of the mind which regulates all the automatic movements of the non-striated muscles; that it presides over the functions of every organ of our bodies, and that it is capable of being reached and directed itself by psychic influences from within and without. To show this psychic relation and control over the peristaltic action of the bowels and the function of defecation, as well also the practicability of relieving habitual constipation, of non-pathologic origin, by psychic methods are the problems set before us in this paper. We are confident, if their solutions are made evident, a flood of light will be thrown upon many other functional derangements and their rational treatment made plain; a treatment too little appreciated and too often flippantly ridiculed and dismissed by thousands of good physicians who have not investigated the worth of suggestive therapeutics.

Peristalsis and defecation.—The essential physical element in the act of defecation is peristalsis. A clear understanding of this function is of vital importance in this discussion. Peristalsis may be defined as a peculiar rhythmic contraction of successive muscular fibers of the intestine. This undulating movement extends through the length of the canal and is called the peristaltic wave. It is less active in the large than in the small intestine. Its function in the upper bowel is, 1, to assist in mixing the food from the stomach with bile and the digestive ferments of the pancreas and intestinal glands; 2, to bring nutrient matter in contact with large absorbing surfaces, and

3, to impel waste material toward the lower bowel. In the large intestine and rectum its function is chiefly that of evacuating their contents. The rectum receives its innervation through the rectal plexus of the sympathetic system. Its communication with the cord and spinal ganglia lies through the sacral plexus. Its communication with cerebral centers lies through the hypogastric and the solar plexus, and reaches the brain through the pneumogastric nerve. Thus the muscular structure of the intestines is connected by two routes with the central nervous system, from which all primal impulses emanate.

The act of defecation is accomplished by the increased peristalsis of the descending colon, sigmoid flexure and rectum upon their fecal contents, assisted by the fixation of the diaphragm and voluntary pressure of the abdominal muscles. We have said the essential physical element in the evacuation of the bowels is peristalsis. Let us bear in mind that normally it is a rhythmic, physical force; that the mechanism, nervous and muscular, by which the phenomena of peristalsis and defecation are accomplished are necessarily dominated by an intelligent, regulating mentality, which sends out these impulses to rhythmic action.

Peristaltic stimuli.—Any agent which promotes peristalsis will favor evacuation of the bowels. This stimulus may be: 1. *Mechanical*, acting on the peripheral termini of the sympathetic nerves, which convey their impressions to the central intelligence, which in turn sends out its motor peristaltic impulses. Such a stimulus is normally excited by the presence of feces in the lower bowel, by foreign substances like seeds, bran of wheat, oats or corn, by ptomaines from bacterial life or protozoa, by massage and physical exercise. 2. *Thermic*, as seen in excessive peristalsis of diarrhea from extremes of atmospheric temperature. Brief applications of hot or cold compress or enema will arouse peristalsis. 3. *Electric*. 4. *Chemical*, by the physiologic action of drugs, the details of which would be out of place here. We may dismiss them all as temporizing expedients, whose effects are fleeting while the habit remains uncured. It is safe to say the bulk of the drug trade centers about aperients, laxatives, cathartics and purgatives, exploited by the commercial enterprise of proprietary medicine men, self-prescribed by the laity or directed by the apothecary or profession, all for the relief of chronic constipation. And so the drugging goes on as it has for ages, while the specific drug is yet undiscovered that will cure the constipated habit. Why? For the simple reason that it is a habit. Habits are psychic affairs and not amenable to the physiologic action of drugs. This leads us to the most important agent of all. 5. *Psychologic*. Every day experience teaches us that the intestinal canal is often profoundly acted upon by mental states. Many nervous people have peristaltic unrest. The excitement of certain emotions, anxiety, fear, anger and the like are soon followed by an action of the bowels, which may even become a diarrhea. Many actors, singers and public speakers are greatly annoyed in this manner as a result of "stage fright." Emotional people sometimes have what is termed "hysterical diarrhea." When a person is in a proper state of susceptibility it is possible to cause defecation by the suggestion that at a given time the *feeling* or desire (peristalsis) for stool will occur. All these are purely mental influences and show conclusively that the mind in its manifold properties

has a faculty which presides over the function of peristalsis and that it is susceptible to both internal and external psychic influences.

Etiology of habitual constipation.—a. "Torpidity of the bowels" (Osler) is usually given as a cause of constipation. This is an explanation which does not explain. It is like the logic used before the laws of gravity were understood, when water was said to flow down hill because of its aquosity. Torpidity simply means sluggish or absent peristalsis. The *why* it is so is the *real* cause. This lies beyond the nerves and muscles of the intestinal canal, which are merely the mechanical appliances of a controlling force in the brain. b. "Sedentary habits, particularly in those persons who eat too much and neglect the calls of nature" (Osler). One habit may induce another, but sedentary habits are not the primary cause of constipated habits. Over-eating, on the contrary, should stimulate peristalsis by reason of more bulky stools. In the neglect of the calls of nature, however, lies the *essential cause* of functional or habitual constipation. (With constipation from pathologic causes this paper does not deal.) Contributing factors there may be, but without this neglect, which has its origin in the mental processes of the individual, and hence is psychic, there would be no habit constipation. What is this "call of nature?" We take it to be the periodic, rhythmic peristaltic impulse which has been directed by that subconscious faculty of the mind which controls the sympathetic system, and is incited to action by various reflex stimuli for the physiologic purpose of defecation. The voluntary co-operation of the individual with these "calls of nature" must be reasonably prompt or the rhythm becomes disturbed, the "calls" less imperative, less regular and in the end functional constipation is the penalty. Nature defeated in her plans becomes inhibitory. The patient must now resort to many artificial expedients to coax the "feeling" back again. Dietetic and hygienic measures, physical exercise and massage, electricity and drugs may be contributing aids, but the essential factor in setting up once more the disturbed rhythmic impulses must necessarily be the re-establishing of *psychic* control. This fact is overlooked in our textbooks in the treatment of this ailment.

To speak of chronic constipation as a mental and not a physical disorder may at first thought seem rather amusing. Some who have given the subject little consideration, will dismiss the idea as ridiculous. Let them still be joined to their cathartic idols. The overwhelming proof that it is so, is the fact that psycho-therapy is capable of re-establishing the function in a great many individuals without the aid of drugs or accessories. The truth of my proposition that habitual constipation is psychic and not physical in its causation is half way acknowledged (though unconsciously) in the conventional instructions given patients to observe faithfully a regular time for going to stool, and whether the desire is present or not, to persist in going through the motions, with the hope that the "feeling" will eventually return with regularity. Did it ever occur to these practitioners that such a method is very effective mental suggestion? That in their therapeutic wanderings they had finally erected an altar to the unknown God? Him would we declare to you.

Osler says "Much may be done by systematic habits, particularly in the young. The desire to go to stool should always be granted." A careful inquiry

into the habits of constipated people will elicit the fact that they have been negligent in this very essential. Especially is this true of women patients, who are the greater sufferers from constipation. For psychologic reasons they sin grievously against themselves in neglecting a function which can be normal only when its rhythm is heeded. A woman, for trivial considerations, easily defers this call "to a more convenient season." By environment and disposition she is less systematic than a man. A neighborly gossip, a household affair, a feeling of repugnance or downright indolence will often interfere with this important duty. Front door vanity and cosmetic effects are often more important, to her way of thinking, than back door sanitation and rules of health. She is quite apt to look upon defecation as a disagreeable nuisance, to be avoided when possible, to be hurried through with or incomplected when necessity arises. No wonder a function which normally should be a real pleasure, and productive of a sense of comfort and well being, becomes an irregular, straining, pile-producing effort. And so with the established ills of induced constipation the victim resorts to cathartic teas, syrups, powders and pills for a relief which can only be temporary.

We wish to give emphasis to the fact that *habit* is a very large word. That all habits, whatever their tendencies, are of psychic origin. That in habitual constipation, with or without other therapeutic aids, suggestion or psychic influence in some form is the only efficient agent that can re-establish a rhythmic peristaltic habit.

We have shown how peristalsis may be accomplished artificially by the temporizing stimuli of drugs, etc., and they have their proper uses as well as their abuses, but there can be no cure of habit constipation until the initial psychic impulses become once more automatic. The drug has not been found, and, from the nature of the case, never can be found, that will re-establish an intuitive mental impulse. Of necessity drugging will go on as a make-shift in perpetuity, until the profession recognizes the psychology of habits and their only possible cure by psychic means.

REPORT OF A CASE OF EPIDEMIC CEREBRO-SPINAL MENINGITIS WITH RECOVERY FOLLOWING LUMBAR PUNCTURE.

BY PETER BASSOE, M.D.

INTERNE IN THE SERVICE OF PROF. GEO. F. BUTLER, COOK COUNTY HOSPITAL, CHICAGO, ILL.

In the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for July 2, Dr. J. B. Herrick reports a case of cerebro-spinal meningitis, in the postmortem of which the diplococcus intracellularis meningitis of Weichselbaum was demonstrated in the meningeal exudate. From this fact and from the large number of cases of meningitis observed in Chicago during the last months, the Doctor concludes that we have to deal with a mild epidemic, although the micro-organism had never been demonstrated before, probably because a bacteriologic examination has been made in but very few cases.

The following case further proves the existence of genuine epidemic meningitis in Chicago at the present time:

The patient, a Russian laborer, 45 years old, previously in

good health, was admitted to treatment under Prof. Geo. F. Butler in the Cook County Hospital, June 17, 1898. Five days before admission he had been suddenly taken with vomiting and diarrhea, followed by severe headache, backache and pain in the extremities. An outside physician sent him to the hospital with the diagnosis of trichinosis. When first seen at the hospital he complained of severe headache; mind was very dull; patient constantly stroked his head and neck with his hands and groaned; great tenderness on pressure; pupils contracted and equal, reacted normally; no ocular or other paralysis; pulse regular, full and soft, 48 beats to the minute; temperature 98, respiration 28; no eruption; examination of chest, abdomen and extremities absolutely negative. The night following admission he was in a continuous pain and stupor; very restless; slept a little under the influence of morphin. The pulse remained slow, 52-64, and the temperature on the day following ranged between 100 and 101 degrees. The bowels were moved by cathartics. During the following days the pulse remained slow, while temperature on the 22d reached 103 degrees, with a pulse of 68. Headache and mild delirium continued. No new symptoms were observed, except a slight right-sided, facial paresis. An ophthalmoscopic examination on the 22d showed no changes in the fundus; there was a marked cupping of the disc on the right side. The delirium became more marked and continuous; headache and tenderness, with rigidity of the neck, persisted; but under the influence of bromide or morphin the patient slept four to six hours during the night. The pulse increased in frequency; on the 25th it ranged from 100 to 120, temperature 100-102.4 degrees.

The diagnosis of meningitis having been made, and in order to ascertain the kind of micro-organism present, a lumbar puncture was made on the 26th. A fine needle was introduced between the second and third lumbar vertebrae, one-half inch from the median line, the cerebro-spinal fluid escaping drop by drop, each drop being distinctly cloudy; 20 c.c. were withdrawn. No change was noticed in the patient's condition during the removal of the fluid. On centrifugalizing the fluid a whitish sediment was obtained, consisting almost exclusively of pus cells, most of them greatly disintegrated. No micro-organisms were seen in or around the cells. Nine human blood serum tubes were inoculated, and on seven no growth appeared. In 36 hours minute drop-like cultures were observed on the two remaining tubes, which under the microscope were seen to be pure cultures of a diplococcus, with occasional titiads. It proved to be the diplococcus intracellularis meningitis of Weichselbaum, and did not stain by Gram's method.

On the day of the puncture the patient's temperature ranged between 99.6 and 100.6; pulse 96-100. The night following he rested better than any night previous and seemed rational in the morning. The temperature next day was 97-99.6; pulse 92-100. Since then the headache, tenderness and rigidity of the neck, and restlessness rapidly have disappeared. On the 28th maximum temperature was 99.2; on the 29th, 98.8; on the 30th it reached 101, but has been normal ever since. On the 27th ophthalmoscopic examination revealed a slight optic neuritis on the right side; only one-fourth of the border of the disc could be made out. On the 29th this was more marked and present to a less degree in the left eye. On July 2nd the optic neuritis was greatly lessened, margins of both discs being distinct. June 28th and the two days following there was urinary retention, so that patient had to be catheterized. July 2nd the patient sat up, had a good appetite and no headache. Since then he has been rapidly gaining in strength and seems to have made a complete recovery.

This case adds another to the number recently reported which go to prove that lumbar puncture not only enables us to make, *intra vitam*, a bacteriological diagnosis of the different varieties of meningitis, but

also that it is the only therapeutic agent which is of more than a palliative value in the treatment of the disease.

SOCIETY PROCEEDINGS.

The Medical Society of the State of New Jersey.

One Hundred and Thirty-second Anniversary at Asbury Park, June 28, 1898.

FIRST DAY.

The session was opened on Tuesday, the 28th, at 3 P.M., with the transaction of much routine business, action upon certain matters relative to the society and reports upon ethics, honorary membership, etc.

In the evening the address of the President, Dr. D. C. English, was delivered.

Dr. English congratulated the Society on its one hundred and thirty-second anniversary, extended a welcome to the visiting brethren from sister societies, returned thanks for the distinguished honor conferred on him by a society that was not only ten years older than the nation, but had a record surpassed by none in devotion to the highest interest of the profession and in loyalty to the State and sacred behests of humanity. He referred to some of the official changes in the Society the past year, especially to the death of Dr. J. J. H. Love and his appointment of Dr. William Pierson in his place as Third Vice-President and Dr. W. J. Chandler in his place as Recording Secretary. He announced his subject as

PATRIOTISM IN THE MEDICAL PROFESSION

as exhibited in the past and as it may find fuller expression in time to come. After defining patriotism he spoke of the four wars through which the nation had passed, culminating in making the country, indeed and in truth, "The land of the free and the home of the brave." He then spoke of the fact that the Society was in session while the fifth great war was in progress, which was partly the reason for the choice of his subject, which he characterized as a righteous war, less selfish than any of the others in that it was fought in others' behalf rather than our own; that England and other nations had permitted the shocking atrocities practiced toward the Armenians; that America had taken the lead and is today the nation that stands for justice, righteousness and humanity, offering to sacrifice her resources of men and money as far as needful to relieve the oppressed. He then proceeded to demonstrate that in no class of citizens had patriotism had greater manifestation or been exhibited with as much unselfish devotion as by the medical profession, and it was considered under two heads: patriotism in times of war and in times of peace. He considered under war, chiefly that of the Revolutionary War, and of that only New Jersey's record, giving much interesting historic data concerning the profession and the part played by it in distinguished position both in the army and the chief positions of influence; showing that advance in medicine and the development of a strong sentiment of patriotism dated from the French and English war (1758-66); giving brief sketches of the fourteen early presidents of the Medical Society of New Jersey, who bore an exceedingly conspicuous part during the war; and also the names of sixty-six others who served ably in the army and in Congress and other civic positions; of the fact entered on society records that because its members were so actively engaged no session was held from 1775 to 1781; that these men were men of culture, of decided religious character and great influence in their respective communities. "These patriots not only fought the battles, gained the victories and secured our independence, but were patriots wise enough and true hearted and virtuous enough to see that victories won and independence gained amounted to but little unless the foundations of the government were laid strong and secure, and that patriots who were true to God, to liberty and righteousness were placed in power to build enduringly. We have observed that these patriotic physicians not only fought well and performed their high and holy mission faithfully, but they served as well in official positions." "They were incorruptible office-holders; they were upright judges; they were politicians in the highest sense of the word, who loved country more than party; they used no corruption fund, and the people were not of that kind who sold their birthright for a mess of pottage." Reference was then made to the War of the Rebellion, giving the members who served and their faithfulness, and fitting reference made to Dr. John Blair Gibbs, the first martyr who fell on Cuban soil in the present war, who formerly lived in New Jersey and was educated at Rutgers College.

Dr. English then spoke of patriotism in times of peace, in which it had its highest, noblest and lifelong manifestations, vastly more important, as peace is preferable to war: the public good, the very purpose for which government exists; of the exhibition often amid struggle, self-denial and often self-sacrifice; the saying that "Peace has its victories no less renowned than war," was not poetic fancy but solid statement of veritable truth. He dwelt upon: 1. Scientific observation and research as involving pecuniary sacrifice, sometimes the sacrifice of life and often reproach and opposition "as fine, sickly sentimentalists and cranks, who in their devotion to a few dumb animals are willing that multitudes of human beings shall suffer and die." 2. Its exhibition in the work of the State Medical Society, which has been purely in the interest of the public and in most cases against the pecuniary interest of the profession. 3. In the cause of education. The work done and acknowledged by educators was dwelt upon. The Doctor urged the teaching in schools of the manner of the spread of contagious diseases and methods of prevention, especially why disinfection and isolation are required, and then impressing by the use of diagrams that sanitary measures are effective. 4. In the cause of state medicine, "preventive medicine is the crowning blessing the medical profession has conferred upon humanity and is the embodiment of the highest type of patriotism the world has ever witnessed, for it is virtually in the final attainment of its aim the profession sacrificing itself." He quoted Professor Gross: "The great question of the day is not this or that operation, not ovariectomy, nor lithotomy, nor hip-joint amputation, which have reflected so much glory upon American medicine—but preventive medicine." He dwelt briefly upon the work in this country and then some of its results, especially in New Jersey, giving the ten leading preventable diseases for the ten years, 1888-98, the great saving of life and what it meant to the State. He urged strongly the introduction throughout the State of the medical inspection of schools, both as one of the most effective measures for the prevention of the spread of contagious diseases and of eye troubles, mentioning what has been accomplished in Boston, New York, Philadelphia, Chicago and elsewhere. 5. Professional charity was briefly and appropriately set forth, the abuse of medical charity well characterized and some good suggestions offered. 6. In political life, medical men in Congress and the State legislatures, their influence, opportunities and duties were briefly considered, as well as their influence and duty in election of good men and securing good legislation. The open saloon with its iniquitous treating customs and political influence, and the curse of syphilis were touched upon. In reference to the National Board of Health the Doctor spoke as follows: "Efforts have been made for years to secure a National Board of Health, which would be of incalculable value and blessing to our country. These efforts, however, have thus far been unsuccessful. We will not discuss the reasons why, but only express our belief that fear that it might interfere with the schemes and ambitions of others, and the failure in a former measure that was defective in conception and plan are the two serious (?) obstacles that are allowed to jeopardize the lives of millions of our citizens. The ambition of no man or body of men should be considered, and as to old failures it is not only puerile argument, but no body of men profit more by the mistakes of the past than medical men. In a letter we received from United States Senator Gallinger recently, he says: "My sincere conviction is that it will be a long time before the legislation you call my attention to is secured. It is much more likely that the Marine-Hospital Service will be granted additional powers and that national health affairs will be kept in the hands of those who are now at the head of that bureau." We are at least thankful that the efforts to secure the national board have stimulated Congress to consider the matter more fully than before and make much larger appropriations for health measures, but we desire Congress, the medical profession and the public to realize that these appropriations have been almost entirely for the merchant marine of the United States, for quarantine purposes, the investigation of epidemic diseases in Havana, etc., under the Marine-Hospital Service, and any additional powers granted will not enable that department to do the systematic and thorough work that a national board of health with proper adjustment of relations with State boards of health would be able to accomplish. The government appropriated in 1896-97 about three-quarters of a million dollars for all public health measures, mainly for the support of the numerous hospitals, the twelve national quarantine stations, investigations, etc., under the Marine-Hospital Service, out of nearly three hundred millions total appropriation. Certainly it would seem if 141 millions could be afforded for pensions and scores of millions for river and harbor improvements in the interest of commerce (and possibly in some

cases to advance political fortunes and aspirations), that at least five millions could be spared and would be most wisely appropriated in caring for the lives and health of the citizens of this great Republic, by the establishment of a national board of health, though no such large sum has been asked or suggested. It seems to us that the question is very largely as to whether the great, the vital interests of the United States in matters pertaining to the public health, shall be circumscribed in their scope and field of operation, and shall be committed to men likely to be swayed by political or personal ambitions, who will seek to build up a strong medical aristocracy with autocratic powers that will enable them to enter any State and exercise their supreme authority over State departments; or whether we shall have a public health department established on a purely scientific basis and conducted by scientific men solely for the advancement of the health interests of this great country, in a manner that shall be in consonance with and shall conserve our republican form of government, and shall in its operations embrace the whole country in the advancement of public health by all measures essential to that end. We believe there should be a Commissioner of public health appointed by the President of the United States, and a Medical Congress or Commission, consisting of one able sanitarian from each State and Territory, appointed by the governor; that they should meet in Washington in brief session, say once in four months; said commission to formulate the laws under which the work shall be carried on, and the Commissioner to carry out such regulations as the Congress or Commission shall establish, with such limited powers as emergent exigencies shall require. It is patent, we think, to every disinterested intelligent person who desires the attainment of the highest and best ends that some such method will avoid, as the Marine-Hospital Service will not, all conflict of authority and lack of co-operation between the United States and the respective States and will insure the greatest efficiency.

In closing, Dr. English urged the display of that patriotism which in its enthusiasm obeys the injunction of wisdom: "Prove all things; hold fast that which is good." He emphasized the need of caution in making or accepting hasty statements of half knowledge, giving two points in illustration: 1. Concerning the general practitioner, because the science of medicine has been wonderfully developing and expanding and knowledge is increasing so rapidly, therefore the general practitioner must go. It is not a logical sequence except in some individual cases. Because the specialist is a one-sided man who magnifies his specialty unduly, brings many cases wrongly within the scope of his specialty, or occasionally treats his brother practitioner non-ethically, therefore the specialist is a fraud and a delusion. It is not a logical conclusion as to specialists in general, though it may have its occasional individual application. He then quoted from Prof. J. M. DaCosta, and endorsed the work of legitimate specialists. 2. Concerning the family physician, his lessened influence was alluded to and deprecated as not being the highest interest of home or country. The address closed with earnest words on the dignity of the profession and the cultivation of the ethical spirit as not only conducive to the highest advancement of the profession, but as the loftiest form of patriotism.

The reports of the standing committees being next in order, Dr. H. W. Elmer read abstracts from the reports received from the several county societies. These consisted of brief accounts of the prevailing diseases in the various sections of the State, the condition of the societies, notices of deaths of prominent members, etc.

THE REPORT ON PROGRESS IN STATE MEDICINE AND HYGIENE,

by Dr. HENRY MITCHELL, Secretary of the State Board of Health, said that the distinguishing feature has been the rapid application of laboratory demonstrations for the prevention of the spread of communicable diseases. New teachings are not accepted so readily as a conservative course begins to prevail. It is still true that the value of sanitation has not penetrated the minds of municipal authorities as it should have done. Local health departments give signs of a more promising course than heretofore. There is a public demand for better organized sanitary service. During the last half century smallpox has decreased 96 per cent. in number of deaths; typhus fever 95; enteric fever 60; scarlet fever 81; phthisis is still too high, though it has fallen 46 per cent. Six hundred thousand persons now reach the age of 21 years who, sixty years ago, would have died. In New Jersey the average duration of life is now fifty-nine years. In the last year the deaths from preventable diseases in the State show a large diminution. Great activity has prevailed in every department of hygiene; the bacteria of tuberculosis, it has been found, will float in the air for five hours. Bacteria are expelled from the mouth by loud speaking, etc.,

but not when the voice is low and gentle. Small movements of the air will waft them about; danger is great from moisture from the mouth and nose of persons at operations, as sneezing, etc., and the patient may infect the air by heavy breathing. Having undergone no attenuation, these bacteria are very virulent. Germano has found live bacteria in dried membranes after four months. His conclusions are: The bacilli of diphtheria can withstand drying for a long time; rapidity in drying does not affect the resisting power; these survive better when surrounded by dust, preventing oxidation; completely dried it retains its virulence till its death; air by dust can carry bacilli while in the living state; so with other bacilli. Ventilation of sewers has attracted attention. It has been found that the air of sewers does not carry bacteria in great numbers. On the contrary, it is singularly free from bacterial life. The odors may be disseminated with no bacteria, hence stench nuisances are not necessarily accompanied by the germs of disease. They may be a warning that danger is not far off. Recent discoveries tend to show that sewer gas only detracts from the breathing of pure air. These investigations may hasten the time when the courts will hold that all conditions which impair the purity of the air are injurious to public health and render the individual less resistant to the real danger when it may chance to occur. Flushing of drains with fresh air dilutes the gases and the danger is minimized. A drain without an intercepting trap is like a house without doors or windows and invites the very evils it was intended to prevent.

It has been found that typhoid fever is not spread by sewer gases. In well constructed sewers the sewage passes away freely and without putrefaction and the air is not unhealthful. Sewage does not form a medium in which growth of typhoid bacilli readily takes place. These undergo destruction in a few days, at most in one or two weeks. Hence the conveyance of this germ by sewer air must be exceptional. Thiroloix has found the bacillus of acute articular rheumatism in the blood of five persons. Intravenous injections of this organism invariably produced cardiac and pleuro-pulmonary lesions. He believes the disease may not always be recognized as rheumatic in character because of the absence of articular inflammation. It has been agreed that the incubation period of bubonic plague should be held at ten days, though it is generally admitted that it is from three to four days. The terms "isolation," "surveillance" and "observation" were defined: Isolation consists in absolute separation of the sick from all uninfected persons. The latter two signify supervision without detention and passengers are allowed to go to their homes, where they can remain under medical care as long as deemed necessary.

Popular interest has been aroused concerning the time-honored but not very acceptable method employed by barbers in carrying on their trade, and much has been written by the profession in condemnation of the application of dirty hands, tools, sponges, brushes, soap, etc., to the faces of the patrons of the barber shop, but in only a few shops have steps been taken toward the introduction of aseptic precautions here. Inquiries among the manufacturers of sterilizing apparatus does not show that any suitable, convenient and efficient appliance for the barbers has yet been offered. These rules may be laid down as an outline of the requirements to which the modern barber should conform in shaving: Clean his hands with soap, water and a nail-brush; apply to the beard soap paste, using only the hands; keep the razor in a sterilizing oven; when dull, do not strop it, use another from the sterilizer; use no large cloth spreads and towels only to protect the garments, no sponges, puffs, pads nor magnesia cake; provide a large sterilizing oven in which the temperature can be kept evenly at 230 degrees and in it keep a supply of towels which have been washed and boiled; use metal combs, wash these after using and keep in sterilizer; hair brushes, if used at all, keep thoroughly washed and clean.

He asked attention to the opportunity now offered in Rutgers College to persons who may desire to pursue the occupation of sanitary inspector, to demonstrate their fitness for this work. Certificates of ability are issued when entitled, and we may hope this will lead to the employment of sanitary officers of a superior type, and inefficient persons will be replaced in time by skillful physicians, etc.

Dr. W. H. IZZARD read the report on

PROGRESS IN MEDICINE AND THERAPEUTICS.

He said: The practice of medicine has materially changed in the last twenty-five years. The subject is broad and lapses into the field of all the branches. He desired only to make a few comparisons between the practice of today and that of a quarter of a century ago. Such teachers as Gross, Pancoast, Wallace, Meigs, Dunglison or Mitchell have not faded much by the shadows of the brilliant men of today. Within the time

mentioned, a specialist was a curiosity, looked upon with suspicion, if not pronounced quacks. Now they are numerous and enjoy perfect freedom and affiliation without question; so much so that most every one afflicted with an affection of the eye, nose, throat, lungs, stomach, intestines, especially in the right side, skin, ovaries, special organs of generation, etc., are sent or go themselves to the specialist, and you see what is left for the general practitioner. If this is progress in medicine, then it has been wonderfully marvelous. Men of my years, covering a period of thirty years, and there are quite a number present, are today to admit the superiority, method, *modus operandi* of medicine and therapeutics, also the wonderful increase of remedial agents over those at our command twenty-five years ago. Then the "Materia Medica" recommended for the textbook contained less than 400 pages, large type; now large volumes containing twice the number of pages and in small type; then the "Dispensatory" was a small book; now almost as large as "Webster's Unabridged;" then it was powders, pills (without sugar) and bitter potions; now the pills are covered with sugar, gelatin, and everything else is compressed into tablets and the rest of the materia medica into sweet palatable elixirs; then we depended upon the pulse to determine the grade of fever; now the thermometer; then we depended upon the lance, quinia and veratrum viride to subdue inflammation; now the lance has become rusty and almost totally discarded and new remedies are employed; then morphia and opium were almost solely depended upon to relieve pain and produce sleep; now we have placed in our hands a score of remedies; then we treated and generally cured diphtheria with nitrate of silver and astringent washes locally and quinin and iron internally; now we use thirty-six to forty-eight hours of time to get a bacteriologic analysis or examination made at Princeton or some other place so we may be sure we have got diphtheria, then a few more hours in getting some genuine fresh and only pure antitoxin, and if we are not in possession of a regulation syringe we spend a little more time in finding some doctor to loan us one, and if our patient is yet alive, we treat him according to advanced medical science; then we used to treat and cure our patients with pain and soreness in the abdomen, especially in the right side, by blisters, mustard, stupes or poultices externally and rest and opiates internally; now we use the knife, a solution of bichlorid of mercury, sponges, needles, thread and a \$500 fee, results not mentioned, all marking the most marvelous progress in medicine; then we successfully treated erysipelas by applying collodium over the affected parts to exclude the air, and quinin and iron internally; now I treat them the same except that I use a mucilage of flaxseed (much cheaper and easier of access) and the quinin and iron internally; I do not know what others use; then we treated eczema, especially herpes zoster, with a solution of nitrate of silver 10 grains to the ounce applied locally with a camel's-hair brush and Fowler's solution internally, with quinin and iron; now the internal treatment ought to be the same.

I might go on through the few remaining diseases left to the general practitioner, but I throw out these few aphorisms to show that the teachings, the study, the practice and the success of the older members should not be too much disregarded, and to point out to the younger members the danger to their patients and themselves, especially the danger of too much experimentation and in hastily using the innumerable new remedies brought to our notice by the journals, and advertising mediums of the manufacturers and others who seek to get rich by the endorsement of honest and honorable members of the profession. I believe in progress and I believe today that the medical profession is doing more to alleviate suffering, to lengthen the days of man, to stop the progress of disease, to avert epidemics and to make man's destiny brighter, happier and healthier, than all the other professions or forces of human organization combined. I would like to have alluded to the admirable sanitary laws and organizations compared with a quarter of a century ago, and to the relegation of epidemics to ancient history, but time will not permit.

Dr. CHARLES YOUNG read a "Report on the Progress in Surgery," a résumé of the various matters that had appeared in the journals during the past year.

"Progress in Diseases of the Throat and Nose and in Eye and Ear Diseases," was reported on by title.

Dr. FAYETTE SMITH read a report on certain diseases. Operations for laryngeal cancer had resulted in most excellent results. Adenoid growths claim much attention and have been found the cause of much trouble, as for instance in cases of inability to talk from infancy; these were found to be the cause and great good was obtained by their removal. In one instance of examination of the pupils of a deaf and dumb institution, 69 per cent. were found to be so afflicted. This is not accidental, there must be a causal relation here. Instances

were mentioned where, by operation, in three months the hearing was improved and a week later talk began, and there was a steady improvement in speech and intellect. It is important that such examinations should be made early to gain all the benefit from the operation. In ozena, diphtheritic antitoxin had been used and it was claimed to be powerfully instrumental in the cure. It demands the continuation of this plan. There is some risk and inconvenience, but it should be demanded. In rhinology there has been little improvement; nasal surgery with its improvements on nature should not be thought of. The best authors insist that milder measures are preferable. Eucaïn is now established as a safe and satisfactory remedy or anesthetic in the throat and nose. There is no danger as with cocain, especially of inebriety; a 4 per cent. solution should be used for examinations, 10 per cent. for operations. In operations on the eye and ear there is more improvement in the technique than in books or instruments.

Dr. B. MEADE BOLTON read a

REPORT ON PROGRESS IN BACTERIOLOGY.

There appeared to be progress in the study of diphtheria, as there was a continual reduction in the mortality since the use of antitoxin. The serum should be the most potent that can be obtained. Much appears to depend upon the article employed. In tuberculosis the sputum taken early in the morning should be used for a test. The danger from sputum is because it is thrown into the air and thus diffused. All do not agree as to finding the bacilli in butter. Bovine tuberculosis is the same as that of man. Typhoid fever shows no improvement in the tests, etc., save the use of Widal's test. In bubonic plague we now have cures up to 95 per cent.

(To be continued.)

PRACTICAL NOTES.

Potassium Iodid in Actinomycosis has not fulfilled the expectations with which it was greeted. Poncet has found it entirely ineffective in eighteen out of twenty-five cases. Sixty were cured, out of eighty recent simple cases, but the iodid was only supplementary to an operation, which is in fact its chief indication. In visceral manifestations the iodid is only useful in the earliest stages. Simple incision and thermocauterization will often suffice to arrest the affection.—*Semaine Méd.*, May 14.

Subcutaneous Injections of Phenic Acid were found very effective by Skultzecki in two cases of severe erysipelas and one of septic puerperal fever; all recovered promptly and he recommends the treatment as strongly as it has already been lauded for tetanus and anthrax. The erysipelas patients received seventy-two to eighty-four injections, a total of 1 gram .44 to 1 gram .68 phenic acid, in a 2 per cent. solution, 1 c.c. every four hours. The puerperal fever was treated with four centigrams of phenic acid every three hours, the first day, and afterward with three centigrams every four hours, for a week, when the cure was complete.—*Semaine Méd.*, May 25.

To Avoid Vesical Complication.—In both men and women, in the healthy state, the urethra in a certain number of cases contains pathogenic bacteria. This is naturally far more common in women. In cases of surgery about the pelvis or rectum, in which catheterization is likely to be needed, the first indication, next to a sterile catheter, is to begin, before the operation, the administration of remedies to make the urine bland and non-irritating. Where this is a routine practice, bladder complications are of great rarity.—*Int. Journal of Surgery*.

Eight Hundred Children Treated with Physiologic Horse Serum.—Solares reports most gratifying success in anemia, chlorosis, chorea, incontinence of urine, scrofula, adenitis, neurasthenia and during convalescence from all diseases, from the administration of physiologic serum from healthy horses, which he has been practicing at the Children's Hospital at Barcelona since June, 1895. He recommends it as a strengthening, stimulating tonic, effective and harmless. The occasional slight, transient, secondary effects observed were similar to those that follow

injections of antitoxin, and probably are due to the same causes. The nutritive processes are powerfully promoted and the nervous system stimulated, but he ascribes its chief tonic properties to the globulins or spermins in serum which accelerate the intra-organic oxidations.—*Revista de Anat. Pat. y Clin.*, April 1.

Puerperal Septicemia Cured with Injections of Sublimate.—Patient 32 years old; placenta previa, hemorrhage and artificial delivery as seven months. Six previous normal deliveries. She received in six days fifteen injections, a total of 0.12 gram sublimate, supplemented by alcohol, quinin, digitalis, ice internally and externally, and permanent irrigation of the uterus with a 1 per thousand sublimate and 3 per cent. phenol solution. Recovery in two weeks. Montini and Perrego, who report the case in the *Gazz. d. Osp. e d. Clin.*, April 3, recommended the sublimate treatment as simple, safe and effective.

Easy Method of Making a Plaster Cast.—A couple of pieces of thin, coarse flannel are dipped in water and spread on a table. The dry plaster is then sprinkled over one of them until it absorbs the moisture and forms a paste which is then smoothed with the hand and worked into the meshes, adding plaster as long as there is moisture to dampen it. The second piece of flannel is then placed on top of it and the same process repeated, when the cast is ready to apply. If a very stiff cast is required a third piece of flannel can be added in the same way. To make it fit over an uneven surface slits can be cut in the flannels, not facing each other. The cast is extremely light and can be folded, removed and fitted closer without breaking. Turpentine or lime-water can be used instead of common water if preferred.—*Revista de Ciencias Méd. de Barcelona*, Oct. 10, 1897.

Water Treatment of Children's Diarrhea.—To remove the cause as rapidly as possible, Mongour first purges and then has the child drink sterilized water, as much as three to four hundred grams a day, with no medication. Vomiting ceases at once, and recovery is complete by the second or third day. Except for those in a moribund condition, all his cases have been cured: 13 hospital, 12 dispensary and 27 in his private practice. Larger has used for several years Vichy water, 2 to 5 liters a day, to counteract the acidity to which he ascribes the trouble. Water treatment prevents the tissues from drying up, and acts like a tonic in much the same way as artificial serum.—*Bulletin Médical*, 20-24.

Antipyrin in the Treatment of Fat Diabetes is the most effective of all remedies, according to the experience of Professor Lemoine. He gives half a gram each of antipyrin and lithium benzoate in a glass of alkaline water three times a day for a fortnight, in cases showing symptoms of intoxication and hepatic insufficiency with diminished secretion of urine and elimination of urea and the characteristic odor of apples in the breath, which warns of impending coma. When the symptoms of intoxication have passed away, he administers 2 to 3 grams of antipyrin in three doses during the day, always in the alkaline water, and 1 gram of lithium carbonate or benzoate twice a day between meals, keeping up the maximum dose of antipyrin for a week and then reducing to 1.5 gram for another week. The treatment is then suspended for a week and resumed for another fortnight, which usually abolishes the last trace of glycosuria. He confirms the cure by administering half a gram each of lithium carbonate and benzoate in alkaline water twice a day half an hour before breakfast and supper, continued for a fortnight every month. If nervous symptoms predominate, he gives only 1.5 to 2 grams antipyrin a day, supplementing it with a tablespoon of the following in a bowl of milk or any unsweetened beverage, an hour before bedtime: Potassium bromid, 40 grams; sodium phosphate, 10 grams; water, 300 grams.—*Semaine Méd.*, May 25.

Blindness in Spain.—One of the principal impressions pro-

duced on those who attended the recent Hygienic Congress in Spain was the large number of blind persons, not only among the beggars, but in all circles, even at the general sessions of the Congress. Hirschberg states that there is not a single professor of ophthalmology in the country, nor any public institution for affections of the eyes, which are treated in the public hospitals or small private institutions. "Owing to their blind fatalism they allow the affection to reach a stage beyond all cure, with no effort to check it, except possibly praying to Saint Lucia." Camuset remarks that in 300 cases which he examined, there were only three or four that were caused by amaurosis; the rest proceeded from neglect during infancy or from granulous inflammation. Six institutions have been founded, but their founders have retired or died and the institutions have lapsed. Hirschberg observes that he never saw so many shriveled eyeballs anywhere, not even in Egypt. The percentage of the blind is larger in the southern provinces. He mentions a street band of nine blind men and also that the custodian of the watch-tower at Cadiz, famous for its magnificent view, was almost totally blind. His only reply to Hirschberg's questions was, "One must be patient."—*Deutsche Med. Woch.*, June 9.

The Schleich Method of General Anesthesia.—Time and experience are confirming the value of the method of general narcosis proposed by C. L. Schleich of Berlin, at the German Congress of Surgery in 1895, which is based on the logical principle that a narcotic substance inhaled is taken up more readily into the circulation and is then eliminated in the exhaled breath the more rapidly and completely, in proportion as the point at which it boils or vaporizes approaches or coincides with the body temperature of the inhaler. A non-vaporized narcotic, such as chloroform, whose boiling point is at 65 degrees C., is absorbed less readily, requiring a larger amount, is retained in the system more, and the task of eliminating it does not devolve upon the proper organ, the lungs, but upon the other parenchymatous organs, especially the liver, which explains the alterations in these organs after death from chloroform. If, on the other hand, a narcotic with a very low boiling point is administered, such as ether (boiling point at 34 degrees C.) the vaporization is so intense at the temperature of the body that it interferes with the respiration, hinders or prevents the dissociation of the respiratory gases, producing cyanosis, retention of the carbon dioxide, which is under less pressure than the super-vaporized ether, and also stretching and tearing the epithelium of the alveoles, leading to secondary pneumonic infiltration. He therefore proposed a triple combination whose boiling or "vaporizing maximum" is identical with the temperature of the body; petroleum ether or benzine (with an established boiling point at 60 to 65 degrees C.), sulphuric ether and chloroform, varying the amount of each in proportion to the rapidity of elimination desired, to secure a higher or lower boiling point. Formula 1. For brief operations. The boiling point, 38 degrees C., co-incides with the internal temperature of the body: Chloroform, 15 parts; petroleum ether, 5; sulphuric ether, 60. Formula 2. For operations requiring a little more time. Boiling point 40 degrees C.: Chloroform, 15; petroleum ether, 5; sulphuric ether, 50. Formula 3. For major operations. Boiling point 42 degrees C.: Chloroform, 30; petroleum ether, 5; sulphuric ether, 80. It is administered with a mask. The sleep induced is prompt and tranquil, resembling more the hypnotic sleep than ether or chloroform narcosis. There is no cyanosis, salivation nor accumulation of mucus nor consecutive pneumonia. There are no counter indications if the lungs are working normally. It has been said, "he has deprived anesthesia of all its dangers." Meyer and Weidig consider even the small proportion of free ether in his formulæ a slight menace, and prefer a solution with the chloroform and ether in molecular combination, which requires petroleum ether with a little lower boiling point.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the *Editor*, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, JULY 23, 1898.

TUBERCULOSIS OF THE MAMMARY GLAND.

Tuberculosis of the mammary gland has heretofore been looked upon as a rare affection. The recent simultaneous reports of four cases of this disease in American medical journals, two by FERGUSON¹ and one by FREIBERG² in this JOURNAL, indicate that the affection may not be as rare as ordinarily supposed. The most extensive of these recent articles upon this subject is that of SCUDDER.³ After making a careful search of the literature he found that there are but eighty instances of tuberculosis of the breast recorded, and twenty-three of these eighty cases lack positive evidence of being tuberculous.

The methods of infection may be enumerated as follows: In primary mammary tuberculosis the bacillus may find its way into the organ through the milk ducts, or through an open wound in the nipple, as in DEMMES'⁴ case or in the skin. Secondary tuberculosis is the most common form. Here the bacillus enters the breast through the blood or through the lymph from foci in some near or distant part of the body. The disease may also arise through extending by contiguity of structure, as from tuberculosis of the rib or sternum, tuberculosis of the pleura, axillary or other neighboring lymphatic glands.

The majority of all the cases were found by SCUDDER to be thirty-five years old or younger. Mammary tuberculosis occurs, therefore, in comparatively young adults; that is to say, during the period of functional

activity of the gland. In about one-half of the cases the women had borne children. Lactation was active during the development of the tubercular disease only a few times. It appears that in the tuberculous puerperal cases there is a greater frequency of suppurative mastitis than in the normal puerperal case, and it would seem that infection with tubercle bacilli would find more favorable soil in a breast once the seat of inflammation. It is an interesting fact to note in passing, that of these eighty cases only six occurred in men.

Among the symptoms, especial mention should be laid upon the fact that in about one-half the cases pain in the breast is mentioned as an early and constant sign. In many cases the patients have sought relief, not so much for the swelling or for the discharging fistulæ that may be present, as for the persistent pain in the breast. In a few cases the nipple was retracted.

The process may show itself in various forms, from a single small nodule or many nodules scattered throughout the breast, to hard irregular masses of varying size, situated in the center or in some segment of the gland. The masses may be movable or fixed. In the majority of the cases the process was slow in its progress, occupying months and years in its course from the time it was first noticed to the time that the disease was examined by a medical man. In SCUDDER's case the duration of the disease was five years. In nearly all the cases the axillary glands presented different stages of tuberculosis. In a considerable number of cases (twenty-nine) tubercle bacilli have been found either in the tissues or in the pus from the abscess.

As regards the diagnosis it will serve the present purpose to state, that tuberculosis of the breast may be confounded with practically every other disease of this organ which may give rise to swelling. Among these conditions are carcinoma and sarcoma, benign tumors, cysts, syphilitic gumma, and actinomycosis. The comparative ease with which a diagnosis of tuberculosis can be reached by means of bacteriologic examination and inoculation experiments does not necessitate a detailed description of the various other points in the differential diagnosis.

As regards treatment the only thorough method is complete removal of the disease, including the whole breast and all the contents of the axilla. The old method of curetting tuberculous abscesses and chronic fistulæ of the breast is not to be depended upon. Radical excision of all diseased tissues, with a wide margin, should be practiced, because tuberculosis may extend further into the surrounding tissues than can be seen with the naked eye. Constitutional and climatic treatment should not be neglected; and the relation of mammary gland tuberculosis in the mother to tuberculosis in the offspring should always be borne in mind by the practitioner

⁴ Quoted by Scudder, loc. cit.

WHAT ARE THE SYMPTOMS OF NEPHRITIS?

A few years ago, when the microscope first began to clear up the mists which pervaded medicine, and when the excretions of the body received attention due them, many observers were not slow in finding in the sediment of the urine bodies which were denominated casts. Some observers went further than this, and a few years ago it was thought possible to differentiate the different varieties of nephritis by the kind of cast found in the urine, attributing the hyalin cast to the interstitial variety and the granular to the parenchymatous. But even before this time the urine had received attention, and albumin had been demonstrated by chemic methods. Clinical experience had told them of the pallor of the skin, of the hardened arteries and of the edema which was sometimes present.

Combining these facts obtained by clinical experience with the occurrence of albumin and casts in the urine it was thought that to make a diagnosis of nephritis was comparatively easy.

But anemia, high arterial tension and edema may be present in other conditions than nephritis, so they only form concomitant symptoms and the diagnosis hinges upon the amount of urine excreted and the presence of albumin and casts in the urine.

When albumin and casts were found in the urine it was thought that this indicated a pathologic condition of the kidneys, but this teaching is gradually being restricted, while some writers have not only given up the idea of making a differentiation of the varieties of nephritis by the kind of casts found, but claim that both albumin and casts are found, even though nephritis be not present. The combination method of Professor HAINES (*vide JOURNAL*, vol. xxx, p. 234), for example, will detect casts in urine normal to coarser tests. Clearly some one is wrong and it is due the profession to adopt some symptom-complex which will settle the question once for all.

It may be that in order to detect albumin some writers have used tests which are extremely delicate, so much so that the faintest trace may be found, while others rely upon the heat and nitric acid test, which is reliable enough for all practical purposes, and why should it be discarded for others which may throw a cloud about the final diagnosis? If casts are found in the urine in health why should we make a diagnosis of diseased kidney when they are present? Now if different varieties of casts are found in all cases of nephritis how can we say that the one is interstitial and the other parenchymatous?

It looks as though the clinical symptoms as observed by the naked eye are taking precedence over the results obtained by microscopic evidence, and clearly there is a fault somewhere. Why not let us say that if albumin is present by some standard test, it indicates nephritis, or if a certain prevailing variety of cast or some other body is found, it indicates the

variety of nephritis? Evidence should not be very hard to obtain and is the duty of those who can do so to set this matter at rest.

EUTHANASIA FOR CONDEMNED CRIMINALS.

In the various countries at different times, diverse methods of inflicting death upon criminals condemned to die have been in vogue for greater or less periods of time. The cruelties of prolonged torture of barbaric days were succeeded by methods at once more rapid and necessarily less painful. Crucifixion with its hours of agony was supplanted by the headman's axe. The guillotine of France, the very name of which caused a shudder to run through civilized Europe, was decidedly less brutal than the cord. Humanitarians in general and many physicians are opposed to hanging as a way of inflicting capital punishment. If one were sure that the neck would always be broken in the drop, there would be some commendable features connected with it; but the sickening struggles of three, four, even five minutes before the attending medical man pronounces life extinct, can not but make one feel that their sufferings are needless and cruel, no matter what their crime may have been. The gaping interest of curiosity seekers in those States where the execution is public; for the great numbers attending hangings, when they can get in, attest more forcibly than words that they derive some sort of entertainment from the spectacle, tends to degrade such persons to as low a level as the central figure of the scene. The latest substitute for hanging, electrocution, has not proved the unqualified success its promulgators had hoped. Death has but in few instances been instantaneous, and many cases stand before us of much longer periods of time used in the completion of the process than has been the case in hanging by strangulation. This delay in a majority of trials has been due to some defect in the apparatus or the interposition of some non-conductor to the electrical current. To be sure execution by this method is done in a comparatively speaking scientific manner, and is robbed of many of the horrors of the hanging, especially the morbid crowd of bystanders, but nevertheless some other method equally "scientific" should be substituted. The beheading with the axe would hardly suffer in comparison with this twentieth century brutality.

At the recent meeting of the Ohio State Medical Society at Columbus, one of the essayists offered in a serio-comic paper, a substitute for hanging and for electrocution, no less than causing dissolution by means of inhalations of chloroform pushed rapidly beyond safety, as indicated by pulse, respirations and pupils. The only objection the essayist could find to the scheme was that the victims would slip their moorings from this earth with thoughts far too pleasant for their hardened minds. This happy condition of affairs however, depends greatly upon the person giving and

the one receiving the anesthetic. One who has given anesthetics to any extent, knows how difficult the patient is to manage in the first stage. His struggles may become so great that four or five strong men may be needed to hold him on the table. We also know that in some cases, continuous saturation of the mask with chloroform is barely sufficient to keep them under, the chloroform apparently having little more effect than so much water; the very next case may be anesthetized easily and promptly, showing that the fault lies not with the chloroform, but in the individual peculiarity of the patient. It is needless to say that it might be rather difficult at times to encompass death in the former instance. Another point, it is against the law of many States for any one to administer an anesthetic except a regularly qualified physician. What physician would be willing to sacrifice himself to the rôle of public executioner? What would become of the practice of such a parasite? A doctor's profession requires him to save life, not take it. He would become so used to death under anesthesia that fatal results would come where he little wished them. To be sure the law might be amended to create the office of non-professional chloroform-executioner. But until incumbents of such offices received considerable training, the beneficent result of an easy, dreamy death as suggested by the essayist would not be forthcoming, for gradual perfect anesthesia is difficult enough in the most skilled hands. How would it look to have the catalogues of our medical colleges embellished with a heading something like the following: "Special Courses given to those who wish to enter the Public Service as Chloroform Executioner. Not necessary to take a course in Medicine."

The remarks of a member of the laity in regard to chloroform anesthesia would perhaps not be out of place (Mrs. KING in the Nineteenth Century for March). She had taken chloroform twice in England and oftener in India. In the latter country the anesthetic was given gradually with plenty of air under the rules as laid down by the Hyderabad commission, and she had never experienced any but the most pleasant sensations. In England, on the other hand, although she was anesthetized by one of the most skilled chloroformists in London, so little air was allowed her that she experienced all the horrors of impending suffocation, and thinks she would have perished had not her heart and lungs been physically sound.

Though the author of the above mentioned article, read at the State society, was not altogether serious in his remarks, nevertheless his subject excited considerable attention, as it is bound to do among all thoughtful persons both in and out of the profession. Substitutes other than chloroform were offered, but none that practice would be likely to prove always efficient, ever ready, painless. Perhaps one of the

best was that the judge should sentence that the condemned man disappear from the eyes of his fellow men on such a day, and that an officer of the court be a witness of the fact and give evidence to that effect: a little hydrocyanic acid in the food and all is over. The terrible uncertainty of the condemned as to his ultimate fate, and the horror excited in the public mind at the very idea of poisoning would be the main difficulties to this scheme. The subject is one of importance to medical men, and it is to be hoped that it will be followed up at other meetings and something evolved which could receive the sanction of physicians generally, and by legislation prevent in time the needless barbarity of the present in the punishment of capital crime.

THE HYGIENE OF MUSIC.

A witty popular writer makes the suggestion that with the growth of utilitarian ideals, music will gradually come to be looked upon, not as a dignified and civilizing art, but as a sort of minor vice; an amiable but enervating dissipation. While there is probably little chance that our ideals will become so completely utilitarian as he suggests, there is nevertheless something in the idea he advances that is perhaps worthy of consideration. It is certainly a curious fact that one form of sensual indulgence, or perhaps one might say more acceptably, sensuous enjoyment, and that as little utilitarian as any, if not absolutely of no value to the race and its continuance, should be lauded as in every way meritorious, even when excessive, while others of far greater real utility are considered, if at all overdone, as hardly respectable, if not absolutely disreputable. This is not because of its intellectual element, for it has as little of that as any form of sensory gratification; it is of itself free enough from any appeal to the intellect to meet the fullest demands of those critics who consider any excitation of the imagination as incompatible with true art. It appeals solely to the emotional and physical sides of our nature and it is a not unreasonable query whether, in so acting, its effects are always and in every way beneficial or desirable.

So much has been said of the therapeutic and generally salutary effects of music; its better side has been so industriously exploited, that it seems unnatural to most individuals to even suggest that it has in it any element of evil, any pathologic possibilities. It is nevertheless true that it has such, and that they are serious enough to be worthy of careful attention. It is not hard to see how and why this can be so if we consider the theories of the origin of music as given by those whose opinions are best worthy of respect. DARWIN's idea that it originates in the sexual impulse and is analogous to the love notes of song birds, is in itself suggestive of such possibilities, and the same is true of that of HERBERT SPENCER, who believes that it originated from the emotional cadences

of speech. WEISMANN has argued that music is a secondary effect on the organs of hearing induced by cultivation, and not in the regular order of nature; in other words, that it is abnormal, hence the ready deduction that it may be related to or give rise to various abnormal and undesirable effects. If we accept it, on the other hand, with WALLASCHEK, as satisfying a rhythmic impulse in our constitution, this really only accounts for one element in music, and that may itself have under some circumstances a morbid as well as a normal effect, and leaves all the others that have been built up upon it to be accounted for, with all their possibilities of good or evil. Taking it as we will and assuming whatever physiologic or other origin for music, there is nothing in it more than a gratification of the senses and an incitation of the feelings. It may be of service as an adjunct to intellectual excitation of the higher emotions as in religious music; it may of itself be soothing in certain conditions of morbid excitement, but it may also be the reverse. The modern classic music and the Wagnerian "music of the future," the degenerative tendencies of which have been so vividly depicted by NORDAU, are harder to justify as beneficial than is the simpler and more melodious music that appeals to the uneducated ear. It is hard, in fact, to see anything but a sort of intoxication in the mental state of some of the musical enthusiasts who go wild over WAGNER'S music, if we can interpret their ideas by the language they employ. It suggests at least a perversion of a sense, a morbid unnatural enjoyment.

Music in itself is not intellectual; its faculty is quite compatible with a profound degree of dementia, as is often shown in asylums and such musical prodigies as Blind Tom, but as an adjunct to poetry in song it often becomes so associated with ideas that we make the mistake of thinking it conveys them itself. As a stirrer of the purely unintellectual emotions it has no rival, and in these two ways lie its possibilities of mischief. Poetry itself is like music in that it appeals to the rhythmic impulse, but it also appeals to the intellect, and not merely to the emotions. Its unhygienic possibilities have long been recognized. One of the greatest poets has said that to appreciate poetry, a trace of morbid mentality was essential, and that this was still more the case to originate it. When music and poetry are combined as is commonly the case the appeal to the emotions is even stronger in many instances, and music without words is, from this common association, most often directly suggestive of ideas that may or may not be healthful.

The actual evil effects of music are less easy to trace because they are generally combined with other causes that get the credit of all the evil. One of the most eminent of English gynecologists has, however, protested strongly against the common practice of musical training of girls as especially disastrous in its consequences, and similar testimony might be obtained in

other quarters. Music has been credited with the production of apoplexy and other nervous affections and is a recognized cause of insanity, though probably to a less extent than is really the case. It is easy to see how its excessive cultivation may be disastrous to hysteric and emotional individuals, and still more often to those who have any decided mental taint.

Music certainly adds much to the enjoyment of life, but it is not a virtue in itself and good as it is, it is liable to be overused and abused. Its hygienic requirements have received too little attention and its pathologic possibilities have been largely ignored. It has its uses in therapeutics, but they hardly outbalance the dangers of its overcultivation, which are real enough even with the simpler music of the past. What they will be with the "music of the future" is as yet an unsolved problem.

THE WAR NEWS OF THE WEEK.

Public interest during the week ending July 16 centered in the surrender of Santiago, Cuba, and the outbreak of yellow fever among the troops investing the city. According to some of the dispatches the infection was brought to El Caney and Siboney by the many thousands of Spanish and Cuban refugees from Santiago; but inasmuch as General MILES considered it advisable to destroy all the buildings at Siboney by fire, it seems evident that this place must have been regarded by his medical officers as a focus of infection. Cases of fever were reported from the time of the first landing of the troops, but these were typhoid and malarial cases, with febrile conditions due to great fatigues and exposures alternately to excessive heat and to the chill of sleeping in wet clothes in the trenches. Ultimately, however, certain cases among men of the Quartermaster's Department, who had been most in contact with the refugees, were recognized as veritable cases of yellow fever; and immediate steps were taken to isolate the cases and prevent the extension of the infection to the troops on the line. On the first notice of the outbreak a large force of immune medical men and nurses, who had been held by Surgeon-General STERNBERG in readiness at Tampa, Florida, for a possibility of the kind, was immediately dispatched to General SHAFER'S command. Meanwhile the reports from the front were discouraging. A special cable dispatch from Siboney to the *Washington Star*, July 14, represented Dr. NICHOLAS SENN as of opinion that in two weeks 25 per cent. of the troops would be *hors de combat*, the sanitary conditions being the worst he had ever seen. Dr. GUITÉRAS, also, was represented as being discouraged. "There are two hundred fever cases here," said this Siboney dispatch, "the majority from the trenches where men sleep night after night in water." The El Caney situation was reported as grave. "There are many cases of fever and great mortality among the people, who are dying from exposure and privation." Santiago.

was represented in all the dispatches as in a most insanitary condition with many of the Spanish troops suffering from fever. But official dispatches from Colonel GREENLEAF, Chief Surgeon on the Staff of General MILES, do not sustain this exaggerated view of the outbreak. On July 16, his statement was: "Only 23 new cases of yellow fever and 3 deaths reported in the last 24 hours; general type of the disease mild; camp sites moved whenever practicable; have taken vigorous sanitary precautions to check the spread of the disease." And on July 16: "Only 16 new cases and 1 death." This is a very grave condition of affairs, but now that the surrender has taken place the troops are in a position to devote the whole of their energies to their protection from infection. The high grounds back of the city are represented as affording dry and well drained camp sites with pure water supplies from mountain streams and the heat tempered by breezes from the sea. Prompt removal of an infected individual to the hospital and prompt removal of a command from an evidently infected camp will, it is hoped, suppress the disease and enable the regiments in a short time to be embarked in as perfect freedom from infection as from a detention station on our own shores.

To meet the possibilities of the future, however, Surgeon General STERNBERG spent some days in New York making arrangements for further strengthening the immune hospital force and providing it with all necessary supplies. On July 16 the Naval Ambulance Ship *Solace* and the transport *Olivette* arrived from Santiago, the former landing sick and wounded soldiers at the General Hospital, Fortress Monroe, Va., and sick and wounded Spanish prisoners at the Naval Hospital, Norfolk, Va.; while the latter, carrying 250 wounded men, was detained off the Quarantine Station at the port of New York by Dr. DOTY, Health Officer, pending an inspection of the condition of the men and the vessel. In this connection, also, the press reports of the terrible conditions existing on the steamer *Harvard*, which brought 1000 prisoners to Portsmouth, are said to have given rise to the keenest apprehension in the Navy Department; but should it be found that yellow fever exists among these prisoners, there ought to be no difficulty in managing it on the New England coast.

Meantime the camps in this country appear to show a decided increase in the prevalence of typhoid fever. Lieutenant-Colonel SMART was called upon to make a careful inspection into, and report upon, the sanitary condition of Camp Alger, Va., giving special attention to the water supply and to the etiology of cases of typhoid fever occurring in that camp, and to Deputy Surgeon-General WOODHULL was assigned the duty of making a similar investigation at Chickamauga Park, Ga., while Major P. R. EGAN has been endeavoring to determine the conditions conducive to the prevalence of typhoid fever in the Fourth Army

Corps at Tampa, Fla. This activity and earnestness on the part of the Medical Department will tend to restrict the ravages of this indigenous camp disease which, although attracting much public attention, is by no means so prevalent as it was in the camps of the early months of the Civil War, July and August, 1861.

TAXING ANTITOXIN.

There is a seeming tendency on the part of certain internal revenue officers to insist that antitoxin comes under the category of the remedies affected by the stamp tax. It is difficult to see how this conclusion can be drawn from the terms and definitions of the recently passed internal revenue law. It is neither a copyrighted remedy (having been presented free, in accordance with the high ethic instinct of the medical profession, to suffering humanity), nor is it a secret preparation put up by pharmacists to resemble copyrighted preparations. Under no construction of the law can it be brought into the category of the class of preparations which congress intended to tax: that is, preparations prepared according to a secret formula guarded by copyright or otherwise for the benefit of corporations or individuals. It is possible, however, that the revenue officers have confounded the antistreptococcic and antidiphtheritic serums with a British proprietary preparation which may fall within the category of the law, but is a totally different preparation. The discussion in congress on this branch of the revenue law clearly showed the legislative intent so far as the taxation of proprietary preparations was concerned. To tax antitoxin in the way proposed would violate not merely the spirit but actual text of the internal revenue act. It will probably be sufficient to indicate these facts to internal revenue officers to avoid such taxation.

CORRESPONDENCE.

Ether Vapor as a Diagnostic Agent.

PEORIA, ILL., July 11, 1898.

To the Editor:—About a year ago I began experimenting with ether as a means of diagnosis of intestinal perforations, and concluded that it would be much more practical and better than hydrogen gas, as advocated by Professor Seun, since it is always at hand and necessitates no special apparatus, aside from what is already found in the surgeon's possession, and further, no objections can be given to its use on account of noxious properties, unfounded as these objections may be as to the hydrogen gas. The quantity of ether being infinitesimal (5j or less being sufficient to give up the necessary vapor, which is diluted many, many times by the air that carries it) absolute freedom from anesthesia is assured. The method is simple: A small quantity of ether is poured into the bottle accompanying the aspirator of so-called French pattern. A soft rubber catheter, or rectal tube (preferably a long glass douche tube connected by rubber tubing), is joined to one of the pipes of the aspirator bottle. The air-pump is joined to the other pipe, and air forced into the bottle becomes mixed with ether vapor and passes on through the alimentary

canal, the rectal tube being inserted as far as necessary. This mixture, which may be called ether-air, rapidly finds its way through the coils of intestines, giving forth strong rumblings as it progresses onward, causing distension on entering the stomach, from whence it is belched, provided no perforation exists along its pathway. Upon reaching a perforation, however, the ether-air escapes into the peritoneal cavity, tympanites more rapidly develops, and upon dilating the wound entrance down to the peritoneum quickly comes out into the world, being at once recognized by its odor and the hissing sound of escaping gas. Upon opening the abdomen the distension of the intestine from the rectum up can be followed to the point of injury where the same odor and hissing are noted and the wound repaired. Continuing the search till no more ether-air is found escaping from the intestines we may rely upon its efficacy.

Case 1.—Dog, thirty pounds; shot through abdomen. The rectal tube was inserted and ether-air forced in. A rumbling along the colon could be followed to the small intestines when tympanites rapidly developed (dog was stimulated by the ether to renewed but weak struggles, although the first shot fired was too high, piercing the heart, the second shot taking effect antero-posteriorly at the middle of the abdomen). At the wound entrance, skin only being enlarged, ether-air escaped quickly with a hissing noise, proving the existence of perforation. The abdomen was opened and three through and through perforations of the small intestines found and four others with only one portion of the gut pierced, each perforation giving out ether-air as the proximal perforations were closed.

Case 2.—Dog, forty pounds; shot in abdomen. A tube was placed in the stomach and the stomach rapidly dilated and the vapor passed a short distance. Tympanites developed rapidly. The abdomen was opened and perforation quickly found in the duodenum.

It might be urged that the rectal administration of such a powerful anesthetic would be fraught with serious dangers, but the quantity of ether is so very small that the small amount of ether vapor given off from it is insignificant in effects, aside from those decidedly beneficial, stimulating the dying to renewed struggles and soothing the system preparatory to treatment.

Case 3.—Live puppy, three pounds. Ether-air was forced through the rectum and out the mouth continuously for an hour. No effects were produced aside from a sense of fullness and seeming happy satisfaction with the overloaded alimentary canal. This process could have continued for unlimited time, but one hour and no anesthetic effects satisfied us there would be none.

EMERSON M. SUTTON, M.D.

Precocious Pregnancy.

CLEVELAND, OHIO, July 16, 1898.

To the Editor:—The letters in the last number of the JOURNAL, on "Precocious Pregnancy," remind me of a case that I saw a couple of years ago. Through the courtesy of my friends, Dr. and Mrs. Lukens, I learned the personal history of the case. The girl menstruated first at the age of 11 years and three months. She immediately became pregnant and was delivered at full term by a rather tedious delivery, although otherwise normal, of a large, well-developed child. Both mother and child did well. The father, at the birth of the baby, was just 14 years old. Sincerely yours,

N. STONE SCOTT, M.D.

Alcohol Injections in Hodgkin's Disease, Etc.

St. Louis, Mo., July 13, 1898.

To the Editor:—The undersigned is preparing a paper on his experience with injection of alcohol in cases of Hodgkin's disease and cancer of the stomach and for the present will only

say that the results thus far have been very encouraging. In due time he will send you a full report for publication.

Respectfully,

A. F. BOCK, M.D.

Reply to Professor Klebs.

CHICAGO, July 19, 1898.

To the Editor:—The following is the reply I wish to make to Professor Klebs' letter beginning: "In consequence of the surprising declaration of Dr. Murphy that tuberculosis of the lungs can be cured, etc."

Professor Klebs has never seen my article, therefore he knows neither my conclusions nor the work on which I base those conclusions, therefore, his letter has no scientific value in connection with my paper. The paper is now appearing in the JOURNAL. I trust that those who have read Professor Klebs' letter will read the paper most carefully.

Very respectfully, J. B. MURPHY, M.D.

BOOK NOTICES.

The Extra Pharmacopeia. Revised in accordance with the "British Pharmacopeia" in 1898. By WILLIAM MARTINDALE, F.L.S., F.C.S. Serotherapy, Organotherapy, Medical References and the Therapeutic Index. By W. WYNN WESCOTT, M.B. Ninth Edition. Price 10s. 6d.

It must be a sad sight to those writers in this country who have always opposed the decimal system to find that British Pharmacopeia now adopts a dual system of weights and measures in all its formulæ except those employed in testing. The British Pharmacopeia states: "The alternative employment in the British Pharmacopeias of 1867 and 1885 of metric weights and measures in the paragraph relating to volumetric analysis is not extended to every official paragraph which makes reference to the usual Imperial weights and measures but the metric system alone is employed in all paragraphs relating to analysis whether the gravimetric or volumetric. During the period of transition from the Imperial to the Metric system a certain amount of confusion is likely to occur."

The editor of this work, Dr. Martindale, says, "To aid the transition, therefore, and to avoid confusion as much as possible we have in a measure followed the commendable precedent of the first official German Pharmacopeia, and of the United States Pharmacopeia of 1883. In either of these with few exceptions parts by weights were employed."

"We have further given in the body of the work the approximate doses of each drug and preparation in terms of the metric system. In further trying to think in the metric system, prescribers may consider the English grain as 65 milligrams (0.065 gram) and $1\frac{1}{2}$ grains as 10 centigrams and 18 minims as approximately 1 cubic centimeter. Following the U. S. Pharmacopeia we have abbreviated the word gram to Gm. and the words cubic centimeter to Cc. The contraction gm. being printed in heavier type and with a capital initial letter, and we recommended it to be written, will distinguish it from gr. the usual contraction for grain. We trust that our readers may soon be able to become familiar with the quantities and doses in terms of the metric system, which it is hoped will ere long supersede the old system. Probably the greatest difficulty will be the introduction of conveniently sized medicine bottles to contain the metric equivalents of the household measures, teaspoonful and tablespoonful."

This work will be found very valuable, especially in regard to the therapeutic uses of the new remedies and the antitoxin.

Transactions of the New York State Medical Association, for the year 1897. Vol. xiv. Cloth. Pp. 646. Published by the Association, New York City.

This volume is edited for the Association by E. D. Ferguson, M.D., and comprises thirty-two papers by leading practitioners; also lists of officers, committees, Fellows, reports of the District Branches, the New York County Medical Association.

tion, necrology and organizations affiliated with the State organization.

Perhaps with the standards of literary and scientific excellence expected from this Association at the start, some of these contributions to the relief of bellicose New Yorkers might have been omitted. Still the controversialists of both sides will have excellent entertainment in the lazy days of vacation. Dr. E. H. Squibb gives his "Brief Comments on the *Materia Medica, Pharmacy and Therapeutics* of the year ending October 1, 1897." Besides the classical address of the President, Dr. Charles Phelps, there are valuable papers by the editor, Drs. Douglas Ayers, Charles E. Lockwood, J. D. Bryant, Parker Syme, Frederick S. Dennis, Ely Van de Werker, A. Palmer Dudley, Ira Van Giesse, George T. Harrison and H. D. Didama. The article on "Medical Expert Testimony," by Dr. H. O. Jewett, is timely, and another by Dr. Samuel W. Smith, on "Acute Catarrh of the Middle Ear as a Sequel of La Grippe," is more than suggestive. Three active members, usually well represented by papers at nearly every meeting, have been removed by death, to-wit, Drs. Wm. T. Lusk, J. Lewis Smith, and W. H. Robb. Of the former, two memorial tributes have been added by Drs. Austin Flint and John Shrady. Much more in praise might be written, but future readers, as well as the affiliated State societies, may expect to be gainers in reprints, journal abstracts and attractively bound volumes. The New York State Medical Association has a just conception of its duties and responsibilities.

Cardiac Failure and Its Treatment, with especial reference to the Use of Baths and Exercise. By ALEXANDER MORISON, M.D., Edinburgh. Pp. 256. London: The Rehman Publishing Company. 1897.

"It is the peculiar merit of those who are responsible for the attention now given to the balneologic and gymnastic treatment of chronic heart disease that they have extended into the domain of active therapeutics, and during the progress of cardiac failure, the roborant influences of that exercise which formerly and in greatest measures found its place in the period of convalescence."

It is well known to every practitioner that many cases of heart disease are apparently conducive to longevity, for they induce less carelessness of diet, regular habits of life and such exercise that the patient lives to a green old age, notwithstanding the existence of his affection. Schott and others have held conclusively that the enfeebled heart may be strengthened in suitable cases by baths and gymnastics and skilfully administered exercise.

This book enters fully into the details of this form of treatment. The illustrations are clear and fully illustrate the work. The pathology of the affection is given from the standpoint of the modern physiologist. We recommend the book as being in every way satisfactory.

Notes on Military Hygiene for Officers of the Line.—A Syllabus of Lectures formerly delivered at the United States Infantry and Cavalry School, by ALFRED A. WOODHULL, LL.D., Lieutenant-Colonel, Medical Department, U. S. Army. New edition, revised and augmented. Pp. 181. New York: John Wiley & Sons. London: Chapman & Hall. 1898.

"These notes," says the author, "represent the essence of the lectures on military hygiene delivered to the class of 1889 at the Infantry and Cavalry School. It was originally prepared for the convenience of the student officers, but it was afterwards thought that it might be acceptable to officers of the line generally. The new edition changes the original edition to correspond with the present army regulations and the progress of sanitary science."

The volunteer officers, particularly of the Medical Department as well as the line, will find very much useful information in this work. Indeed, it will be well nigh indispensable to those for the first time having the responsibility and care of troops.

Atlas and Abstract of the Diseases of the Larynx.—By Dr. L. GRUNWALD of Munich. Authorized translation from the German and edited by Charles P. Grayson, M.D. 107 colored figures on 44 plates. Philadelphia: W. B. Saunders. 1898. Price \$2.50 net.

"This Atlas," says the translator, "exemplifies a happy blending of the didactic and clinical such as is scarcely to be found in any other volume on this subject with which we are acquainted. It is upon the value of the clinical portion of the work that the editor would dwell with particular emphasis."

The beginner will find here a series of pathologic conditions illustrated with a remarkable fidelity to nature, "that it would require him a number of years to duplicate in actual practice, while the veteran, however rich his experience, will note a precision, a *finesse* in diagnosis that can not fail to be instructive, perhaps even inspiring."

Most of the illustrations were prepared by the academic painter, Mr. Keilitz, from sketches or preparations by the author.

The Methodist Episcopal Hospital Reports. Volume i. 1887-1897. By LEWIS STEPHEN PILCHER, M.D., GLENTWORTH REEVE BUTLER, M.D., New York. Published by the Hospital in 1898.

The book is divided into four parts, viz.:

Part I. 1. Historical Notes, by John Storry Breckinridge, M.D. 2. The Building and the Administrative and the Medical Organization of the Hospital, by Eugene Allen Noble. 3. List of the officers and others connected with the Hospital from its organization.

Part II. Surgical Reports. This comprises various surgical essays, by Lewis Stephen Pilcher, M.D., George Ryerson Fowler, M.D., James P. Warbasse, M.D., Thomas Bray Spence, M.D., Charles Henry Goodrich, M.D., Henry Goodwin Webster, M.D., William Nathan Belcher, M.D.

Part III. Medical Reports. By Alexander Ross Matheson, M.D., Glentworth Reeve Butler, M.D., William Nathan Belcher, M.D., Ralph Melville Mead, M.D., Frank Whitfield Shad, M.D., Arthur Henry Bogart, M.D., Charles Richard Butler, M.D., Henry Goodwin Webster, M.D., Raymond Clark, M.D., Henry Pelouse de Forest, M.D.

Part IV. Pediatric Reports. By John Biou Bogart, M.D. The Hospital was opened for the reception of patients, Dec. 15, 1887, and this report is a record of the decade of hospital work. The book is handsomely printed.

Atlas of Legal Medicine. By Dr. E. VAN HOFMANN. Authorized translation from the German, edited by FREDERICK PETERSON, M.D., assisted by ALOYSIUS P. J. KELLY, M.D. Fifty-six plates in colors and 193 illustrations in black. Philadelphia: W. B. Saunders. 1898. Price \$3.50 net.

The illustrations in this work are original, having been prepared from recent cases or from museum specimens. The volume is made up chiefly of photographs and drawings of various lesions and pathologic conditions taken from actual cases such as would take one many years to acquire unaided. The illustrations cover suffocation, criminal malpractice, injuries of the brain, fracture of the skull, poisoning by mineral acids, arsenic, etc. This reference atlas will be found invaluable.

ASSOCIATION NEWS.

Medical Colleges.—The Permanent Secretary has issued the following circular:

PHILADELPHIA, JUNE 30, 1898.

Dear Sir:—At the recent meeting of this Association the following was unanimously adopted:

WHEREAS, the AMERICAN MEDICAL ASSOCIATION did, at Detroit in 1892, unanimously resolve to demand of all the medical colleges of the United States the adoption and observance of a standard of requirements of all candidates for the degree of doctor of medicine which should in no manner fall below the minimum standard of the Association of American Medical Colleges; and

WHEREAS, this demand was sent officially by Permanent Secretary to the deans of every medical college in the United States and to every medical journal in the United States, now therefore the AMERICAN MEDICAL ASSOCIATION gives notice that hereafter no professor or other teacher in, nor any graduate of, any medical college in the United States, which shall after January 1, 1899, confer the degree of doctor of medicine or receive such degree on any conditions below the published standard of the Association of American Medical Colleges, shall be allowed to register as either delegate or permanent member of this ASSOCIATION.

Resolved, that the Permanent Secretary shall within thirty days after this meeting send a certified copy of these resolutions to the dean of each medical college in the United States and to each medical journal in the United States.

Respectfully yours,

WM. B. ATKINSON, Permanent Secretary.

Please acknowledge receipt of these resolutions.

The Columbus Meeting.

COLUMBUS, OHIO, July 13, 1898.

To the Editor:—We have at once entered actively upon the preparation for entertaining our guests, the AMERICAN MEDICAL ASSOCIATION, in 1899, and can assure them we will leave nothing undone which can contribute to their comfort. Our hotels are as anxious as we are that the meeting shall be a grand success. They offer the following rates and accommodations respectively; Great Southern, rates \$2.50 to \$4.00, American plan. Chittenden, \$2.50 to \$4.00, American plan. Neil, \$2.50 to \$3.00, American plan. Park, \$1.50 to \$2.50, American plan. Davidson, \$2.50 per day, American plan. Hotel Goodale, .75 to \$1.00 per day for room, European plan, first-class restaurant attached. Smith's European, \$1.00 to \$1.50 per day per room, European plan, first-class restaurant attached. Normandie, \$1.50 per day, American plan. Norwich, \$1.50 per day, American plan.

In addition to these regular hotels, we have a large number of strictly first-class boarding-houses where many guests can find economical and comfortable accommodations. A careful canvass of the above hotels mentioned, assures us that they can comfortably accommodate 2500 guests, and with our other facilities we will have no trouble in comfortably entertaining all who will come.

STARLING LOVING,

Chairman Committee of Arrangements.

The Denver Meeting—Comments of the Medical Press.

AND the same day it rained—and the next day—and the day after.

The registration amounted to over 1,300, second, we believe, only to the semi-centennial at Philadelphia, which it was hardly expected to excel. The opening general session was marked by lively interest and good fellow feeling. The remarks of Governor Adams, while amusing, were tinged with truth. The address of Surgeon-General Sternberg did not, of course, receive the same consideration as if he had delivered it in person. But as the reader of the paper, Lieut. Woodhull, remarked, the possibility of absence is one of the penalties that must sometimes be paid when high-grade men are chosen for such offices. After the first day the attendance at the general session was not nearly what it might have been to attain the best results for the good of the society. For example, a total vote counted at mid-session on the second day numbered only 216. However, our visitors from the east can hardly be blamed for wishing to see new sights rather than to listen to discussions on topics that may be more or less stale to them. Besides it will all be in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. . . . The final general session was enlivened by a heated discussion over the long mooted question of the admission of the heretical New York societies. The Philadelphians made a gallant stand for the affirmative, but the self-styled conservatives were in the majority against them. As a matter of fact there is a great deal of sanctimonious cant about the Code, and those who preach it most loudly are as a rule the ones that practice it least. The practical details of the Code are almost never observed. For example, is there one physician in a thousand who, when called to supersede another in a given case, assures himself that the former attendant has been paid in full for his services? When we take a bird's-eye view of the Code it appears to us much like a placard asking gentle-

men not to spit upon the floor. In the sections is where the actual work of the Association is accomplished. Here meet the gray-bearded octogenarian and the beardless boyish graduate, the man of brains and the man of skill and the man who has neither—all brought together in the wholesome fraternal occupation of giving and taking information. Here may be found a congenial atmosphere for all sorts of souls—from the village-prayer-meeting-like quiet of dietetics and physiology to the rousing and militant acclaim of surgery. And now why was it that the gynecology and surgery sections attracted more of an audience, perhaps, than all the other sections put together? Is it that we are all becoming specialists, or is it rather that the general practitioner seeks in such sources the secret of that prestige which has not been his? The few resolutions that were introduced in general sessions were, generally speaking, both timely and proper. One of the most noteworthy was that by Dr. Gould, favoring the establishment of medical libraries throughout the country. The seven years of labor for a National cabinet department of public health should be furthered to its goal by the thousand-dollar appropriation for the special committee on this department. Dr. Sanders' resolution for a National public health system, applicable to all parts of the United States, had its special object lesson no doubt, in the yellow fever imbroglis of the past summer.—*Denver Med. Times*.

THE meeting of the American Medical Association held at Denver during last week can not be regarded as other than most successful. The fact that many of the local medical men originally came from the east led to the renewal of many old acquaintanceships, and this, combined with the hospitable welcome extended by the citizens of Denver, increased the feeling among the visitors that they were indeed at home. Then, too, the situation of the "City of the Plains," surrounded as it is by many features of peculiar interest to medical men, served to stimulate the activity of body and mind and to give the proceedings, scientific and social, a zest not to be found at less favorable meeting-places. The railroad and hotel accommodations were unusually good, and thus one of the most common sources of dissatisfaction was avoided, while the good-will of the visitors was obtained at the start by the efficient methods instituted for the registration of members. The meeting-halls were conveniently situated, unusually large and well ventilated, and with few exceptions their acoustic properties were good. The meeting was also very representative of the Association as a whole, for all sections of the country sent delegates to represent their views, with the result that the proceedings really represented the National profession as a whole. This general representative meeting, therefore, far surpassed in importance to the profession some of its predecessors which have had a local color, and emphasizes the fact that the American Medical Association is becoming more powerful for good in the medical affairs of the country. Sectional differences are disappearing, and politics, while active, is gradually decreasing in importance as scientific pursuits become more popular. An innovation of importance was that of asking most of the members in Denver on Monday night to the dinner tendered to the Medical Editors' Association. By this means the whole assembly started with a swing which carried it through the meeting, and friendships were formed which did much toward increasing the good feeling which was so apparent on every hand. The work of the general sections was good, and the papers in many instances were discussed in a manner which showed that their hearers had ideas worth expression and worthy of respectful attention. This was particularly true of the sections on medicine, surgery and gynecology, in which animated and spirited debates were constantly going on. Aside from the general educational effects of the meeting there can be no doubt that it will exercise a good effect by informing many physicians of the exact therapeutic properties of the Colorado climate; for the program prepared for the entertainment of visitors was designed by the railroads and hotels to advance one's views of the possibilities of the consumptive's paradise.—*Med. News, N. Y.*

BUT the features of the Denver meeting that will stand out most strongly in the memory of those who attended it were the entertainments and excursions. These began with the arrival of visiting members, but first rose to full dignity and form in the dinner of the American Academy of Medicine on Saturday evening, when the Governor of the State and the heads of the Colorado State University, of Boulder; the University of Denver, and the Colorado Springs College, and the President of the Woman's Club of Denver, with the fellows of the Academy responded to toasts, and between the toasts the whole company, nearly half ladies, joined in singing college songs. Sun-

day, the entertainments were quieter but none the less enjoyable, Monday evening they blossomed out in the Medical Editors' banquet, with Hare to preside, and Patterson of the *Rocky Mountain News*, Love, Mercy, Keen, N. S. Davis, Jr., J. W. Holland, J. M. Matthews, Hamilton, Wheaton and others to respond to toasts. Tuesday evening the Section dinners were more largely attended than they ever have been before, over 500 members of the Association joining in them, 175 at the joint dinner of the Sections on Surgery, and Obstetrics and Diseases of Women, 83 at the dinner of the Section on Stomatology. Thanks to the efforts of Dr. E. C. Rivers and others who had the matter in charge, the future of the section dinner is assured. Wednesday evening came the great reception given by the Colorado State Medical Society at the Brown Palace Hotel, and Thursday evening the receptions by the Denver and Arapahoe County Medical Society at the residence of its president, Dr. E. P. Hershey, and at the residences of other prominent citizens of Denver. On Friday an opportunity to study climatology was given in an excursion up Clear Creek Canon to Silver Plume, 9200 feet above sea level. Over 1700 doctors and members of their families were handled in seven trains on this narrow gauge railroad, given a lunch at Idaho Springs of full Western quantity and that would rate as of first quality in any Eastern city, and treated to some of the grandest mountain scenery in the world; and everything moved with perfect smoothness, to the complete satisfaction of the guests.—*Phila. Polyclinic*.

AFTER a year of tedious detail work and much anxiety the Denver meeting came, and has gone into the past. Over 1500 physicians from all parts of the United States were in attendance, and over 500 ladies accompanied them. . . . The first of the mountain outings, which came as a relaxation after the heavy scientific work of the week, was the trip over the Loop which gave the doctors and their friends a very startling introduction to mountain scenery. The trip up Clear Creek Canon is one of continuous delight and amazement, and the "Kodak fiend" was kept busy trying to get a snap at all the beautiful views. Impressions, whether good or bad, of Colorado, were carried away that day by the wholesale. Our visitors had already marveled at Denver's hospitality, but the reception given them at a stop-over at Idaho Springs, only added to their incredulity. The people of that town were fairly teeming with hospitality and from the time the guests entered the town until they left, they owned the place, and a visit from Li Hung Chang himself couldn't have aroused more enthusiasm, in the townspeople than did these visitors. . . . One day in the mountains only whetted their appetite for more and the trip to Colorado Springs the following day was just as well patronized. The Colorado Midland and the Denver and Rio Grande carried about 1500 doctors and their friends to the Pike's Peak region, and Colorado Springs people served luncheon to the guests at the Coburn Library; then the guests were taken to the various points of interest and the day was ended by a grand ball at Manitou. Then came a general scattering to Cripple Creek, Glenwood Springs, Salt Lake and other places. The quiet lull that has settled over Denver is the natural consequence of the week of excitement which kept every one busy and active. The profession of Denver and Colorado have enjoyed entertaining the visiting brethren, and they feel well repaid for the energies put forth which has made the meeting the grand success every one pronounces it to be. The only complaint heard is that Denver has set a pace for hospitality and entertaining which will be hard for the other cities who entertain the American Medical Association in the future to keep up with.—*Colo. Med. Jour.*

THE meeting of the American Medical Association in Denver this year was an important event in the affairs of the local profession and the visitors were very handsomely entertained during their sojourn in Colorado. While the number in attendance was far below what was expected, yet the meeting as a whole was considered fairly successful. The arrangements of the local committee were very complete and gave entire satisfaction to their guests. The work of the Association seemed to be well in hand and, except an occasional ripple, everything went along smoothly enough. The question of admitting the wayward New York brethren was revived by Dr. H. A. Hare, on the third day, and but for the fact that the presiding officer ruled the doctor out of order, after a very heated discussion, it is doubtful what the result of a vote would have been. Certainly the house seemed about evenly divided. The most notable paper presented at this session was one by Dr. J. B. Murphy of Chicago, on the "Cure of Consumption by Compression of the Lung." This was indeed a very interesting feature of the meeting and one well calculated to elicit im-

mediate and universal attention. Dr. Murphy's claim that he had and could cure pulmonary tuberculosis by compressing the lung through the introduction of nitrogen into the chest cavity in such quantity as to give the lung tissue complete rest for a few weeks, was a startling proposition and created great enthusiasm. The subject is too new for intelligent discussion at this time, but the doctor is confident in his premises, which, he says, are based on successful experimentation. Should his claims be substantiated, some queer conjectures and deductions must follow in regard to prevailing theories regarding tuberculosis, and especially in regard to the germ theory.—*The Critique* (homeo.).

THE Denver meeting of the American Medical Association was in many respects one of the most enjoyable meetings ever held by that body. The profession and people of Denver did everything to make the meeting the grand success which it proved to be. The dinners, receptions and entertainments were of a very high order and unusually enjoyable, but there is a growing feeling that these entertainments should be curtailed, as they take a great deal of time that might be employed to much better advantage in the work of the Association. The suggestion made in the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* that the general sessions be held at night, in lieu of the receptions, strikes us as a good one. . . . The large number who attended the Denver meeting shows what great interest the profession at large feel in the American Medical Association to go in such numbers to such a distance to attend the meeting. It is a very great privilege to be a member of the American Medical Association, and while the Association is growing in strength and numbers every year, it should include in its membership every reputable physician in the United States. By becoming a permanent member one avails himself of all the privileges of the Association and gets one of the very best medical journals, if not the best, published in the United States, all for \$5.00 per annum.—*Atlanta Med. and Surg. Jour.*

THERE are three things which prompt a physician to leave his practice for an extended trip to attend the meetings of the American Medical Association,—interest in the scientific work of the Association, the pleasure of meeting old friends and seeing and hearing prominent men of the profession, and the enjoyment of travel and a visit to new parts of the country. In all these particulars the Denver trip has been eminently successful, and I have yet to hear of anything but praise for the forty-ninth annual meeting. We had all heard of the climate of Colorado, yet we began to hear of it anew as soon as the limits of that State were reached. Everybody praised it, everybody asked how you liked it, and every local man in every speech or public utterance laid stress upon it. . . . Yet there was one thing in greater abundance than the climate, and that was hospitality. Nothing more could have been done for the entertainment of the visitors. Receptions and excursions were almost too abundant. A desire to enjoy them at times interfered with the attendance upon the sessions of the Association, and on Friday, at the closing general meeting, there was but a corporal's guard of those interested in the politics of the A. M. A. It is no easy task to arrange for the entertainment of 2000 people, yet the work of the various committees was admirable. To be sure there will be some among such a large number of guests who fail to appreciate the hospitality, and show by their actions their lack of good breeding. To my knowledge there were few examples, but one was at the reception tendered to the ladies and the visit to the smelter. . . . Some of the visitors failed to appreciate the labors of the committees and objected because the street cars were not free, and two, to my personal knowledge, made a decided kick against paying two dollars and a quarter for a dinner, room and breakfast in a six-dollar-a-day hotel, saying that they had been told the rate was but two dollars. These trivial things must be expected, and but serve to add a sort of spice to the general enjoyment. Speaking of hotels, there are in Denver good hotels and bad ones, and it may be that because my acquaintanceship is limited, I met more people who had the bad ones. There was a good deal of complaint at three or four of the hotels over the accommodation and the table, and some who were paying \$3.00 and \$3.50 per day even went to restaurants to get a square meal. I know I did, and had it not been for the generous banquets on the first two nights, and the hospitable receptions following, I should have left Denver hungry. . . . The program for the different Sections was very full, and had there been in attendance as many as were there represented there would not have been time for each paper, but many of the prominent men whose names appeared were not present. The character

of the work done was of the highest order, and although no strikingly new theory was presented, the discussions were animated and profitable. Dr. J. M. Mathews of Louisville, Ky., was elected President for the ensuing year, and Columbus, O., was selected as the next place of meeting. Apparently such a program was cut and dried for the occasion with all the quickness of the drying powers of Colorado air, for there was no opposition. This is as it should be; politics should have no place in the A. M. A., but nevertheless it usually has an important one.—*Atlanta Med. Weekly*.

THE Denver meeting of the American Medical Association will forever live in the memory of those who were in attendance as the most complete in every detail in recent years. While the Philadelphia meeting may never be surpassed in the magnitude of work accomplished and the number of physicians present, yet in the uniqueness of the manifold attractions aside from the scientific work of the meeting, Denver seemingly has capped the climax. This is largely the result of the peculiar, favorable location and the bountiful spirit of hospitality, for which the Denver and Colorado profession are well-known. The success of the Denver meeting is due primarily to the local committee of arrangements, in Denver, which, under the wise and pushing direction of Dr. Graham, successfully engineered this most gigantic undertaking in a way that will forever redound to the credit of Western medicine, and Denver hospitality in particular. Denver, certainly is the Queen City of the West, and the grand State of Colorado a State of great and unlimited resources. But above all, it is the climate with which this State is blessed which makes it of interest to physicians, for it says to the weary and afflicted of the East, come and rest in the God-given sanitarium, where health will be given you and wealth, too, if in patience and good-will you but pursue the even tenor of your way. The evidences of the good that comes from a change of residence to those afflicted with pulmonary disease is apparent in almost all localities of Colorado. And such cumulative revelations appeal to physicians, and give to them renewed hope for the many cases constantly coming under their observation. The American Medical Association naturally must feel under lasting obligations to their Colorado brethren for the opportunity of meeting in Denver, just for this one impressive fact alone. The main interest of the physicians in attendance, however, was centered in the work of the Association, which was characterized by an abundance of scientific papers and thoroughness of their discussion in the several sections. In the general sessions many important measures were adopted, the chief of which was the determination to bring within the domain of standard recognition certain medical colleges which have, thus far, failed to qualify, and the means adopted was that of barring from membership in the Association members of the faculty of these schools, which fail to conform to the requirements of the Association of American Medical Colleges. The attempt to reconcile the Medical Society of the State of New York with the Association failed once more, and as a result this old sore must continue to suppurate until some wise measure may, in the future, be adopted which will give to the Association the valuable membership, which must come when peace shall be declared between these bodies. . . . Taking it all in all, we hardly expect to see the like of the Denver meeting again. It was unique, superb and scientific, and all who attended were well repaid many times over for the time and money spent in the pursuit of knowledge, experience and a good time. . . . *Med. Fortnightly*.

UNDER the lengthened shadows of the Rockies lies the most beautiful and charming city of the Union, Denver, the pride and glory of Colorado and the modern Palmyra of the plains. One does not tire in looking on its magnificent structures, public and private, nor can he repress surprise and admiration, if he would, at the spirit and grit of the citizens, who allow no obstacle to bar the way to a still higher eminence which becomes more pronounced as the years throw into her lap the wealth that still flows from the ores mined in the neighboring hills. As its climate is invigorating, so is the spirit that has reared on the western plain a city that rivals that of "the Chaldees' excellency." Thither went the leading lights of the profession, in the first week of June, from every State in the Union, and there gathered in associations that have for their object the highest interests of the profession as well as those that are related to the welfare of others. The American Medical Association was the chief magnet around which gathered others whose aim and work looks in the same direction, chief of which was the Association of American Medical Colleges. Its aim and work are of no less importance, because primary and fundamental, preliminary to that of the Association

of physicians. The two associations are very closely connected, and each endeavors to contribute to the efficiency of the other. This was shown by an action of the Medical Association when it adopted a course of action which excludes from its membership the professors of any medical college which does not make its entrance requirements and terms of instruction conform to those prescribed for its membership by the Association of American Medical Colleges. The result of this action will be that no professor of a college can become a member of the American Medical Association, nor the college in which one is a professor become a member of the Association of American Medical Colleges, unless the college adopts the requirements made by the Association. This action places the mark of Cain on all wanderers from the path of professional ethics in the beginning and at the end. Now if State medical associations shall take like action, some bodies will get squeezed out. The entertainments provided by the local profession were all that could be desired, and so timed were they that they did not interfere with the legitimate work of the Associations represented.—*Med. Herald*.

THE meeting was large beyond most persons' expectations; it was also exceptionally representative, for those in attendance were for the most part men of mature age, without the large element of recent graduates usually encountered. The social accessories were enjoyable and to a great extent novel. Enthusiasm and good-fellowship prevailed to a degree unsurpassed, so far as we know, at any of the Association's previous meetings. It is safe to say that the fair city of Denver has proved its capability of taking good care of a large number of visitors; it has also shown its willingness to do so. It was thought by a number of persons that at this meeting some way would be found to reconcile the differences existing between the Association and the Medical Society of the State of New York. We lately expressed some reserve on this point, and the result justifies our lack of faith. Nothing has been done to restore the former relations of the two organizations. Nevertheless, a way was pointed out by the President, in his address, whereby individual members of the profession might join the Association without regard to their State affiliations. It would apply, however, only to those who might be willing to subscribe to the Association's Code of Ethics. Still, it would doubtless let in a great many desirable men, and it seems probable that some such plan will be adopted sooner or later. One of the most important achievements of the meeting was the passage of a measure barring from membership, after a certain date, all physicians who are members of a teaching staff of any medical school that does not conform to the requirements of the Association of American Medical Colleges. The result of this will be to force all the medical schools of the country to adopt the four years' course, on pain of being unrepresented in the Association. It has taken many years to accomplish the enactment of such a measure, and the Association is to be congratulated on its adoption at last. The scientific work done in the Section meetings was quite up to the standard, and the meeting may be said to have been eminently satisfactory from this point of view.—*New York Medical Journal*.

WE do not believe that the exhibitors at the American Medical Association are ever treated right. They contribute very much to the interest of the Association; the exhibitors constitute a very important feature of this meeting. We understand that at the Denver meeting not one of them received a ticket for the excursion around the Loop; they were not invited to attend the receptions. The gentlemen attending and in charge of these exhibits are in every sense of the word gentlemen. They, as a rule, are men who have traveled; they are men well educated, at home in good society and we believe that they should receive more recognition and should have more courtesies extended to them than they received at the Denver meeting. We do not mention these facts to find fault with the Committee of Arrangements, but to find fault with the way that they are and have been treated at the meetings of the American Medical Association, and trust that they will be treated differently at the Columbus meeting. The next place of meeting will be Columbus, Ohio. Judging by the members of the Columbus profession present at the Denver meeting, the American Medical Profession will be well taken care of next year. The new code bobs up in a general session and bobs down. It is unfortunate that the medical profession of New York is not in full sympathy with the American Medical Association. Whether the new code is right or wrong, we believe that some concessions on both sides are desirable. We trust that between now and the Columbus meeting something may occur which will bring about the burial of the hatchet.—*Denver Med. Times*.

THE meeting of the American Medical Association at Denver was a decided success in every particular. More than 1500 members were registered as delegates, with fully 500 non-registered doctors in attendance; and nearly 1000 visiting ladies. The section work was good, notably in the surgical and gynecological departments, in the latter fully 300 members being often present. There was practically no friction in either section, the debates being of highly interesting character, without personalities. The two subjects which elicited most interest were the remedy proposed by Dr. John B. Murphy of Chicago, for pulmonary tuberculosis, and the discussion on the relation of pelvic diseases to insanity and other nervous affections, participated in by the neurologists and the gynecologists. . . . The joint discussion by the gynecologists and neurologists showed that there is a tendency for the two to come together; that is, no gynecologist can succeed in curing a large percentage of his cases unless he has a pretty thorough knowledge of neurology or works with a neurologist, and no neurologist can properly treat quite a large proportion of his female patients without recourse to gynecological measures. Dr. Joseph Price of Philadelphia was particularly positive that many cases of insanity, as well as epilepsy and other neuroses depend upon gross pelvic lesions, and can be cured only by their removal; and related scores of cases in support of his position.—*Am. Jour. of Surg. and Gyn.*

THE scientific work of most of the Sections was up to the average, but in several the programs were overcrowded, a number of inconsequential papers being allowed to creep in. A more than usual number of absentees from the list of members whose names were on the program for papers was noted. Men who are unable to meet their engagements should make it a point to have their names removed from the Secretary's list of promised papers before such be included in the final program. One of the small annoyances to the audience is the non-appearance of an author whose name and paper have been published far and wide, and who is perhaps one of the principal attractions of the meeting. . . . It is to be hoped that our next meeting will be more productive of original research. The fact that the time of the scientific Sections is cut short during the morning sessions, to allow of attendance upon the general meetings with their political fuss and fol-de-rol, has raised considerable criticism, and it is desirable that more of the general session work be placed in the hands of the Executive Committee, and thus valuable time saved to the scientific Sections.—*Ophthalmic Record.*

THE American Medical Association will hold its meeting of 1899 in Columbus. Our city has been named to follow in the list—Denver, Philadelphia, Atlanta, Baltimore and all those that have preceded. It certainly is an honor to the city and a compliment to the profession and business men who extended the invitation to the Association to come here. The choice is one of responsibility, both for the Association and for the city. The former has expressed its confidence in our representatives, and it now devolves upon us as Columbus citizens and as members of the medical profession, to see that their promises are more than fulfilled. That this will be done we most firmly believe. It means work—painstaking detail work to accomplish this—but it will be after all work of love, and one we have said we only awaited the opportunity to take up. It shall be our endeavor to prove the wisdom of the choice of Columbus, and to the Association the *Columbus Medical Journal* extends the thanks of our citizens for this opportunity to test the virtues of the Buckeye Capital as a convention city.—*Columbus (Ohio) Med. Jour.*

THE American Medical Association may well feel proud of the welcome accorded it in the West, and of the unstinted hospitality displayed by the people of the various localities visited by its members. It was generally agreed that one of the most remarkable of the striking features of the memorable excursion around "the Loop" was the manner in which the people of Idaho Springs received and entertained upward of two thousand visitors. The whole town turned out, ladies, children and all, and made the occasion one huge lawn party, in which all were individually welcomed and made happy; yet it was done with such an absence of apparent effort that the guests became possessed with the notion that such wholesale entertainment must be a part of the every day life of that town. It was one link in a chain of many pleasant recollections which the visiting members carried home with them.—*Med. Record, N. Y.*

VIEWED from every possible standpoint, the meeting of the American Medical Association, at Denver, was the most suc-

cessful in its history. The only other meeting with which it could be compared was the semi-centennial, held at Philadelphia, but since that meeting was in the heart of the most populous section of our country, having fully 30,000 doctors within a radius of fifty miles, and since only a semi-centennial can justly be compared with it, it must be left out of consideration, in which case the Denver meeting goes into history as the banner one. . . . There can be no question that the holding of our National convention in the State of Colorado has been of great service to the profession, as well as to the invalid public. Much definite knowledge has been gained by the members which is practical and valuable, and could not have been secured in any other way. . . .—*Med. Mirror.*

DESPITE the Hispano-American war, the meeting at Denver was a success, and the Association began the second half of its century of existence under most auspicious circumstances. The general meetings were well attended, and the Section meetings were also graced by the presence of many members. From a scientific point of view the meeting was a marked success. It is to be regretted that the present war prevented the President of the Association, Dr. Geo. M. Sternberg, Surgeon-General U.S.A., from being present. His address, which was a masterly one, was read for him during his absence. The 1500 members who were present deplored the necessity of this hiatus. The social features of the meeting were on a grand and magnificent scale, and it will be many years before the Denver meeting is forgotten.—*St. Louis Med. and Surg. Jour.*

DENVER has redeemed her pledges, and the meeting of this Association just closed has been one of the most satisfactory in its history. The very atmosphere of Colorado seemed to be imbued with hospitality. The attendance exceeded all expectations, the registration reaching 1600. In the absence of President Sternberg the chair was gracefully filled by First Vice-president Joseph M. Mathews, M.D., of Kentucky. The entertainments provided by the local committee were not only elaborate but pleasing in the extreme, and the memories of Denver's profession and Colorado's beauty spots will ever remain in the minds of the visiting physicians.—*Med. Fortnightly.*

THIS meeting of the Association was a most successful one in many respects. In numbers it was largely attended, 1100 members having registered at an early hour of the first day. The Treasurer's report shows a very healthy condition and the enrollment of 1500 additional members. The papers read were uniformly interesting and progressive. There seems to have been much less of political action. Dr. Keen's address of last year seems to have done some good. The usual bone of contention, the secretaryship, was left at rest for one time. A number of new measures were introduced, one of which was of great importance, especially in connection with medical education.—*Nashville Jour. of Med. and Surg.*

WE predicted last month that this meeting would be one of unusual worth, and now that it is past, we can say it is doubtful if in the history of medicine there has ever been a meeting of more general interest or one more entitled to be justly and unreservedly termed successful. The efforts of the Denver physicians were Herculean, and their success was complete, even to detail. . . . The work of the sections was in many instances far above the average. Several papers in each section might be mentioned as being of especial interest, but our limited space precludes the possibility of giving even a brief abstract of those which merit notice. Inasmuch as they will be published, and as doubtless all of our readers are members of the Association, or, if not, they should be, they will thus get the benefit of at least reading them.—*Chicago Clinic.*

THE Denver meeting will pass into medical history as one of the most pleasant, enjoyable and profitable meetings the Association has yet held. The arrangements were well carried out, and the various sections carried out their programs on schedule time and were well attended. The registration reached twelve hundred on Tuesday, a remarkably large number when it is remembered that many of our members are now in the service of the United States government.—*Ala. Med. and Surg. Age.*

THE meeting of the American Medical Association in Denver was an unqualified success, and the meeting of the Ophthalmological Section was up to its usual standard, although the familiar faces of Knapp, Risley, de Schweinitz and others were much missed. The humorists of the Section, Drs. Thompson of Indianapolis and Savage of Nashville were there, and added their usual welcome flavoring to the proceedings of

the Section. Drs. Black, Rivers and others of Denver did much to make the meeting successful in adding to the comfort of their fellow ophthalmologists and earned their deepest gratitude.—*Ophthalmic Record*.

THE Association convened in Denver on June 7. Considering the location of the meeting, making it necessary for many to travel a long distance, the attendance was quite large and representative of the ablest and most progressive elements in the organization. The Sections were well attended, and the long list of papers presented in each by leading members indicated the depth of interest in the work, and the fact that each branch of medical science is receiving due attention from the Association.—*Medical Standard*.

THE forty-ninth annual meeting of the American Medical Association at Denver, June 7-10, was attended by a representative of the *Lancet* in order to let our readers have an early and complete account of the meeting. From the expression of all who attended, we believe the meeting was as pleasant and profitable as any that has ever been held. The attendance was large, there being over 1500 registered. . . . To dwell on all the notable features of the meeting is impossible. The discussion of appendicitis in the Surgical Section prominently participated in by Drs. Keen and Murphy was probably the feature of the meeting. All the Sections were well attended and profitable, the Section dinners and receptions extremely pleasant and altogether the Denver physicians and the Denver people did all in their power to make the meeting a memorable one.—*Memphis Lancet*.

THE meeting of the American Medical Association at Denver this year has been in every way successful and progressive. With a single exception, referred to elsewhere, there has been no striking discovery made public, but work in all the Sections has been more serious and solid than has before been customary. The growing popularity and power of the Association were made plain by the increased membership. The registration this year has been 1322, this number being next to the largest in the history of the organization.—*British Medical Journal*.

THE Denver meeting will pass into medical history as one of the most pleasant, enjoyable and profitable meetings the Association has yet held; the arrangements were well carried out and the various Sections carried out their programs on schedule time and were well attended.—*N. A. Jour. of Diag. and Practice*.

THE meeting just closed was one of the most interesting and profitable and most largely attended in the history of the Association. . . . No doubt this meeting will remain in the memory as one of the pleasantest in the history of the Association.—*Annals of Gyn. and Ped.*

NEVER in the history of this Association has a more pleasant and profitable meeting been held, than that which closed at Denver June 10.—*Kansas City Med. Index*.

NECROLOGY.

JOHN BOARDMAN, M.D., Buffalo, N. Y., died July 9, aged 70 years. He was graduated from the Medical Department of the University of California in 1853 and, later, was for two years demonstrator of anatomy in the Medical Department of the University of Buffalo, from 1854 to 1858 physician to the Buffalo Orphan Asylum, and attending surgeon to the Buffalo Hospital of the Sisters of Charity from 1856 to 1873. In 1883 he was appointed on the board of managers of the Buffalo State Hospital for the Insane. He served on the board until 1891, when he resigned, owing to ill health.

GEORGE W. BURTON, M.D., Mitchell, Ind., July 13.—William B. Cochran, M.D., Middleburg, Va., aged 89 years.—Andrew J. Hare, M.D., Milwaukee, July 6, aged 60 years. David S. Hayes, M.D., Hollidaysburg, Pa., July 10, aged 65 years.—Charles L. Knowlton, M.D., Northampton, Mass., July 5, aged 74 years.—E. A. Parkinson, M.D., Hart, Mich., July 12.—Frank G. Seaman, M.D., Seneca Falls, N. Y., July 12, aged 35 years.—J. J. Warren, M.D., Sharon, July 1.

WARREN PIERCE, M.D., Plymouth, Mass., died July 10, aged 50 years. July 29, 1862, he enlisted in Company K, Fourteenth Massachusetts Regiment, as a private. He was detailed as hospital steward soon after and served two years in that position, when he was appointed second lieutenant of the Fifty-sixth United States colored infantry, stationed at Fort Lookout, where 5000 Confederate prisoners were confined. In July, 1864, his regiment was attached to the Twenty-fifth Army Corps and ordered to the front at Petersburg. Lieutenant Pierce took part in the operations against Richmond and was the third Federal soldier to enter that city. He was graduated from Harvard Medical School in 1869.

WILLIAM HENRY HODGMAN, M.D., College Physicians and Surgeons, N. Y., 1873, died at Saratoga, N. Y., July 15, aged 46 years. He was health officer of Saratoga Springs from 1878 to 1879.

MISCELLANY.

Prof. Daniel R. Brower of Chicago has been elected as a foreign member of the Moscow Society of Neurology and Mental Science.

A Common Complaint.—“What are you treating me for, doctor?” “Loss of memory. You have owed me a bill of \$10 for two years.”—*Tid-Bits*.

THE Souvenir Volume presented to Professor Durante of Rome on the twenty-fifth anniversary of his professorship, contained 2000 pages in the three volumes, and sixty original communications, including one on the resection of the Gasserian ganglion by Keen and Spiller of Philadelphia, and one by Biunie of Kansas City, on encapsulated epithelioma.

Quarantine Burned.—From the *Register*, Mobile, Ala., we learn that the quarantine plant, located in the lower bay, a mile above Fort Morgan, caught fire July 8, and the main building was destroyed. The amount of insurance on the plant was \$13,240. The plant was built in 1892 and cost about \$60,000. Of the amount required for its erection the State of Alabama appropriated \$50,000.

War Correspondence.—The readers of the JOURNAL will regret that Lieutenant-Colonel Senn's correspondence last week was sent to the *Chicago Record*, and the letter of this week was sent to the *Chicago Tribune*. As they appeared in those papers before we could get them in type, we were unable to use them. The manuscript which we received has been sent to the Newberry Library.

Surgical Treatment of Sterility.—Mann (*Annals of Gyn. and Ped.*, July), in discussing this subject, enumerates the causes of this condition as vaginismus, atresia of the vagina, stenosis of the os, lacerations of the cervix, uterine displacements, endometritis and adenomatous disease, cervical catarrh and tumors. He considers the only relief as surgery, modern surgical methods implying practically no danger in this class of operations.

Plastic Operations on the Tubes.—Ries (*Annals of Gyn. and Ped.*, July), believes that the conviction that too many tubes have been removed is gaining ground, and plastic operations on the tubes are being resorted to instead. He considers plastic operations indicated in obstruction of the tubal channel by benignant tumors, extra-uterine pregnancy in certain cases, and “inflammation in cases where there is no pus or other signs of an active stage of the inflammation.” Diagnosis of such occlusion may be difficult.

Hip Joint Amputation.—Noble, in *Annals of Surgery* for June, reports six cases of hip-joint amputation: One injured by crushing high up in the thigh; two from disease of the bone involving the head of the femur and acetabulum; three and made for osteosarcoma in the tibia. Two were done by trans-

fixion, and three by the use of Wyeth's pins. On account of the objection to the latter method, *i. e.*, "that when the pressure is removed, the amount of blood lost from the oozing of small vessels is perhaps greater than in any other means," he believes the trephining method is the best.

An Editorial Change.—The *Annals of Gynecology and Pediatrics*, for June, announces that hereafter Dr. B. Sherwood-Dunn will be jointly interested in the editing and publishing of that journal. Dr. Dunn was graduated at Bellevue Hospital Medical College, New York, 1884, and from the academic department of the University of France, Paris, in 1887, and the medical department of the same university in 1888. He has also had several years' hospital experience in Paris, and in 1897, in recognition of his work in France, was decorated by the French government with the cross of *Officier d'Académie*.

Operative Wounds of the Thoracic Duct.—Cushing, in *Annals of Surgery* for June, summarizes seven cases collected from the literature and adds to these two from the surgical records of the Johns Hopkins Hospital. If the duct itself is injured, he considers suture the ideal method, but only in cases where the duct is fully exposed and not completely divided. He advises placing a ligature about the duct on the proximal side of the wound, and control the leakage by a gauze tampon. This would act as a safety-valve and allow the chyle to escape if the pressure in the duct became too great. If the leakage should become uncontrollable, the ligature should be tied in an effort to readjust the collateral circulation, trusting for some branch to carry the lymph into the venous circulation.

Lactic Acid in Arthritis Deformans.—Zolotorin, *La Med. mod.*, Vol. ix, in a case of ten years' standing, the last year of which the patient kept her bed, began with ten drops on an empty stomach, no food being allowed for an hour and a half afterward, and gradually increased the dose to forty drops a day. In three weeks the woman could get out of bed and walk a little, the pains being much relieved and the joint circumference slightly diminished. The improvement lasted until no care was required, and ordinary duties could be resumed. No internal medicine other than lactic acid was given, and no external placebo except slight massage.

Fortress Monroe as a Hospital Point.—The present indications are that Fortress Monroe is to be made an important center for the care of the sick and wounded during the present war. A corps of twenty surgeons has already been detailed for duty as a beginning, and the large wooden building, at first proposed, is likely to be superseded by tents with ample conveniences. These are to be located on the moat near the fort hospital building, and the superiority of the place, as demonstrated in the civil war, is again to be corroborated. Yellow fever, although regarded by the citizens of Tampa and other points on the Florida coast as a possible source of anxiety, especially at this season, has not thus far ranked as a menacing objection of any magnitude. Still it is not certain that the infected will be brought to Old Point when farther North so easily minimizes the difficulties. Every confidence in the wisdom of the Executive, however, is freely expressed.

Blastomycosis of the Skin is the name proposed by Buschke for a new affection described by him at the recent German Dermatologic Congress, with microscopic demonstrations of one case. It is a primary disease of the skin, due to pathogenic blastomycetes, clinically resembling carcinoma, but without its hard edges, histologically belonging to the granulation tumors, and anatomically occupying a middle ground between mycosis and infective granulation tumors. Infection of the blood may lead to the formation of internal tumors, but the skin is the chosen site and entering point even for internal manifestations. He considers the existence of primary intestinal blastomycosis also probable. The existence of pathogenic yeast fungi is established, belonging to the saccharomy-

cetes and oidii, but nothing indicates their connection with malignant tumors.—*Munch Med. Woch.*, June 21.

Spanish Cruelties.—Curses, like chickens, come home to roost. Some enthusiastic Cuban has delved in the old Spanish libraries and from a number of books has photographed the wood cuts made at the time, selecting those which illustrate the cruelty of greed of that nation. They form a collection about as grewsome and hideous as the famous chamber of horrors in Brussels. In one picture the methods employed by Pizarro and Cortez to compel the poor Aztecs to reveal the source of their wealth are shown. The favorite system was to stretch a man on the ground between two posts and then to build a fire near the soles of his feet. Another was to set fierce hounds upon a man. The terrible part of the story is that these practices were not done underhandedly, but openly, by their perpetrators, and the drawings were put in these old books to show how ingenious and efficient the system was.—*New York Mail and Express*.

Melancholia.—Loveland in the *New York Medical Journal* of June 25 presents a contribution on this subject, accompanied by a table showing the results of an examination of the blood in fifty-seven cases. He considers the main feature of the treatment, feeding, sometimes forced feeding with liquid food, and in the fifty-seven cases, concluded from the study of the blood that it was neither deficient in hemoglobin nor hemocytes at the initial or early stage of the disorder; in fact, he found it above the average in these particulars. He says: "That after the loss of appetite, always present, and the frequent entire refusal to take food, and the impaired digestive power associated with such a mental condition, the blood first loses its richness in coloring matter, and later in the corpuscular elements." He considers it a circumstance worthy of note that while many people with thick blood are melancholy, he has never seen any signs of melancholia in profoundly anemic cases.

Albumosuria in Medical Practice.—In the *American Journal of the Medical Sciences* for July, Fitz reports a case of myxedema in which albumosuria continued throughout the progress of the disease, a symptom which, with but a single exception, has hitherto been unrecorded. He says that while transitory albumosuria has proven of but "little practical value except in the diagnosis of acute pneumonia, deep-seated suppuration, including meningitis, and of macerated fetus," greater value is to be attached to persistent albumosuria, and its importance has been especially suggested during late years in the diagnosis of multiple but latent tumors of the trunk, principally multiple bone tumors and in myxedema, and in but few cases of these affections. "Whatever the value of albumosuria may be in diagnosis, its persistent and excessive presence is apparently a sign of grave prognosis, since the cases in which this condition has been found have, almost without exception, proven fatal."

Jaundice in Typhoid Fever.—In the *American Journal of the Medical Sciences* for July, Da Costa presents observations made on this subject in the Pennsylvania Hospital during the past winter. In some of the cases jaundice was associated with parotid swelling, which he considers more than a coincidence. In some it occurred as a late symptom and in one case, which he considers unique, it distinctively preceded the development of typhoid fever, occurring during the latter part of the incubation period. Previous to the five cases reported, he has met with but one instance of jaundice in typhoid fever, although jaundice is not infrequent when there is a complication of malaria. He finds that the symptoms attending jaundice are not constant, but as a rule the symptoms of a severe case of typhoid fever. Delirium is apt to be present, but it was not much aggravated by hepatic conditions, and there were intervals when the mind was clear. High temperature was the rule,

chills not uncommon, and the pulse remained rapid. He believes that jaundice in such cases is usually due to a blood condition, with more or less disorganization of the red corpuscles and often associated with alteration in the liver cells. All the cases reported show the symptom to be a grave one, the fifty-two cases resulting in thirty-three deaths and nineteen recoveries.

Micro-organisms Resembling the Tubercle Bacillus have been isolated by A. Moeller from timothy and other grass and the fresh droppings of the domestic animals. Inoculated into rabbits they produce a miliary tuberculosis, nodules in the omentum, giant cells, cheesy patches in the lungs, deceptively similar to the lesions of genuine tuberculosis. Other animals and a few rabbits were not affected by them. His preliminary communication in the *Deutsche Med. Woch.* of June 16 describes their rapid, dry growth, yellow sediment, and resistance to alcohol. They stain like the tubercle bacillus, which they closely resemble morphologically and in their growth on glycerin agar. On bouillon this micro-organism forms a delicate, transparent, dry, pale yellow skin on the water, extending 2 to 3 cm. up the glass. Shaking the tube breaks off fragments which sink to the bottom. He concludes by detailing the points in which this "timothy bacillus" differs from others in its growth, etc.

The Wounded in this and the Previous War.—Surgeon-General William K. Van Reypen, United States Navy, according to the Washington lay press dispatches "has received a report from the surgeons with the fleet that in the many cases of wounded, some of them serious, not a rise of temperature nor an accumulation of pus has appeared in any case. From a medical standpoint this is said to be a marked advance from the conditions during the Civil War, and is attributed to the introduction of antiseptic treatment of wounds." An old army surgeon in the confidence of the *JOURNAL* excepts to this statement in part, for he maintains that "in the Civil War the most exemplary cleanliness was enforced in the hospitals, and that the method of irrigation was adopted from the start; further, that there was a rivalry among the ward-masters of the pavilion tents as regards the best appointments and comforts. This was certainly the case in the Western divisions of the army, where private mansions and close quarters were from the first tabooed. Certainly proper drainage was always the aim in the treatment of suppurating wounds." Much talk in reference to "laudable pus" was the vogue, but was generally looked upon as a significant sign of ultimate recovery. In fact, he says: "To some it was an 'unknown god,' ignorantly worshiped." To all of which may not the statement be added that in the matter of antiseptics there are many makeshifts which scarcely baffle the Anglo-Saxon mind. It may be recalled that bromine, when introduced by Surgeon Goldsmith, vanquished the hospital-gangrene occasionally prevalent.

A German Medico-Legal Decision.—The so-called "Seidel case" (a trial for libel), recently terminated at Brunswick, Germany, was a remarkable judicial proceeding, unlike anything met with in the courts in America or England. The Government of Brunswick and certain assistants in the Brunswick General Hospital united in prosecuting the brothers of the late Dr. Seidel, one of the attending surgeons in that institution, for publishing a charge to the effect that he had been impelled to commit suicide by the intrigues and falsehoods of his assistants and by the severity of the Government in suspending the professor from his hospital functions before he had been heard in his own defense. The trial excited great interest in the medical profession in Germany, and many eminent surgeons testified as experts, the weight of opinion being strongly in favor of the correctness of the late Dr. Seidel's conduct and against the manner in which he had been treated by the assistants in the hospital. Their principal grievance against him appears to have been his indifference to antiseptic precautions in surgery, but the expert witnesses declared that the assist-

ants had exaggerated ideas on this subject. The court in the end acquitted the brothers of Dr. Seidel and declared that the accusations against the deceased surgeon were unjust.

The Unsung Heroes.—Dewey and Bagley and Hobson and Schley and Blue and Neville and Shaw, the heroes of Guatanamo, Capron and Shafter, and all the long list of men who have distinguished themselves in this war, officers and men, are deserving of all the generous praise that has been bestowed upon them for the brave deeds they have done and for their unflinching devotion to duty. Their example is of inestimable value for its influence upon their fellow-citizens both in civil and military life. They are a source of inspiration which tends to a higher order of patriotism in all the walks of life and all the duties of the citizen. The patriotic uplift is discoverable to the most distant part of the country, and in the remotest hamlet. It manifests itself in greater love for the flag, greater pride in citizenship, greater fidelity to civic duties. War is a great character-maker. The heroes of the field and of the wave are its exemplars, and under the spell of hero-worship men grow better. All honor to the Deweys and Hobeons and the rest of them. Yet there is one class of heroes whose praises are seldom sung and whose patriotic sacrifices receive but slight recognition in the dispatches from the front. But they are there, exposed in greater or less degree to the fortunes of war, doing their duty without hope of acknowledgment, and performing their daily and nightly tasks with a devotion that knows no flagging, and without the spur and the inspiration of the cavalry charge or the shriek and crash of the flying shells on board the man of war. The surgeon's duties on the field and in the hospital tent preclude the incentive of excitement, and are attended by none of the dramatic action of war. No matter what the conditions, whether for the time in comparative safety or when his scene of operations becomes the center of the hottest fire, as sometimes happens, he stands to his post, offering his own that he may save the life of another. While remembering the heroes of the sabre and the gun, do not forget the heroes of the scalpel and the probe. They are never court-martialed for cowardice. And no wonder. Bravery in the face of danger is no new thing for them. The volunteer surgeon has not learned courage and ceased to be afraid because of any "baptism of fire." He has faced danger before. The faithful and skillful doctor is always in the thickest of the fight in the battle of life. He has learned all there is to be learned of bravery and self-sacrifice in the midst of the deadly epidemic, and in the panic of pestilence and plague he acquired the courage which makes a hero of him now. God bless the doctors! They are the salt of the earth. No class of men see so much of the suffering and misery of life; none do so much to relieve distress without hope of reward in this world. And the doctors at the front—congress passes no resolutions of thanks to them, and presidents and public do not applaud their fidelity to duty. Why, then, are they there? What glory awaits their efforts? Their only reward is the satisfaction of duty done; the approval of their own consciousness that their skill and experience and their limit of endurance have been spent without hesitation in the service of their country and in behalf of their fellow men. Remember the men, give praise and honor to sacrifice and courage and steadfastness in the face of the enemy, and remember the unsung heroes, too.—*Minneapolis Journal*, July 14.

Commercial Greatness of the United States.—The Chief of the Bureau of Vital Statistics of the Treasury Department kindly furnishes us the following:

More than three-quarters of the \$1,200,000,000 worth of our productions which were sent abroad during the fiscal year just ended went to Europe, while only one-half of the \$600,000,000 worth which we imported came from Europe. Nearly one-half of our exports of the year went to the United Kingdom alone, while our imports from the United Kingdom were less than one-fifth of our total importations.

While the full figures of the fiscal year are not yet complete, the reports of the Bureau of Statistics covering the eleven months ending June 1 are sufficient to show who have been the purchasers of the enormous aggregation of domestic pro-

ductions which the United States has distributed to the world in this year of her greatest commerce. Our sales to Europe are more than three times as much as our purchases from that part of the world, the exports to Europe during eleven months of the year being \$901,014,786 and the imports from European countries in the same time \$281,091,002. To the countries of North America we have sold 50 per cent. more than we have purchased from them, our exports to them for the eleven months being \$127,125,929, against \$81,287,478 of imports from them. To Africa we have sold more than double the amount of our purchases, the exports to that part of the world being \$16,097,959 in the eleven months whose record is completed, and the imports \$6,786,017. Here the scale turns against us, for in our commerce with South America, Asia and Oceania our sales to each of those countries have been far less than our purchases from them. To South America we sold during the eleven months in question only \$30,748,846 worth, while our purchases from that part of the world were \$85,859,245. To Asia our sales were but \$41,561,531 and our purchases therefrom \$85,381,158. To Oceania our sales were \$19,979,555 and our purchases \$23,365,132. It is gratifying to observe, however, that in our trade with Asia, where all nations of the earth are now striving to extend their commerce, there has been a material gain in our exports during the year, the total being nearly 15 per cent. greater than that of last year.

The figures for the year will show a marked improvement over those of last year, the exports to Europe being more than three times the imports from Europe, while last year they were not quite double the imports; the exports to North American countries will be nearly fifty million dollars in excess of the imports from these countries, while last year the excess of exports was less than twenty million dollars; our imports from South America will be 150 per cent. in excess of our exports to that part of the world, while last year they were more than 200 per cent. greater than the exports.

There is not a country, indeed scarcely a spot, in the civilized portions of the globe which has not been a customer of the United States in the year just ended. From the United Kingdom, whose purchases for the year are nearly six hundred million dollars, down to Paraguay with a total of less than one thousand dollars, the continents, countries and the islands of the earth have purchased of the plenteous supplies which the United States has been able to offer to the world in this greatest year of her commerce. To the United Kingdom the exports for the eleven months were \$501,756,263, against \$452,926,890 in the corresponding months of the preceding year. Germany came next as a purchaser, our total sales to that country being \$143,416,065, against \$116,881,478 last year. The next largest purchaser was France, to which we exported \$87,012,841 in the eleven months of the year, against \$54,575,298 in the corresponding months of the preceding year. Next came British North America with purchases amounting to \$76,160,414, against only \$59,676,594; then Netherlands with \$59,733,226, against \$46,436,034 last year; then Belgium with \$44,006,379, against \$30,469,416 last year; Italy, \$21,849,377, against \$20,205,301 last year; Mexico, \$19,304,687, against \$21,396,395 last year; Japan, \$19,260,415, against \$12,468,433 last year; British Australasia, \$14,213,606, against \$16,197,092 last year; Brazil, \$12,694,163, against \$11,413,345 last year; Denmark, \$11,604,578, against \$9,627,047; British Africa, \$10,953,954, against \$12,216,080; Spain, \$10,193,300, against \$10,208,637, and China, \$9,036,727, against \$10,981,919 last year, while none of the other countries of the world reached the \$10,000,000 line in the eleven months whose record is now complete.

Our purchases abroad, as already indicated, are much less than those of last year, being for the eleven months \$563,770,032, against \$679,557,391, and for the full year likely to be but a trifle in excess of \$600,000,000, against \$764,730,412 last year. This year our total exports will practically double our imports, while last year they were less than 25 per cent. greater than our imports. As above stated, one-half of our importations came from Europe. Our largest purchases during the year were from the United Kingdom, which, as already indicated, was our largest customer, our total purchases in the eleven months from the United Kingdom being \$101,454,480, against \$148,588,675 in the corresponding months of last year. The next largest purchases were from Germany, from which we bought in the eleven months \$61,916,809 worth of goods, against \$98,364,012 last year; Brazil next, from which we bought \$58,203,762, against \$64,695,383 last year; then France, \$49,480,413, against \$60,095,025; British North America, \$28,528,539, against \$34,757,841 last year; and during the eleven months of 1898 we bought \$24,164,842 from British India, \$23,180,892 from Japan, \$19,484,387 from China, \$18,209,368 from Italy, and \$16,142,491 from Mexico.

The following table gives our exports to, and imports from

the grand divisions of the world during the eleven months ending June 1, 1898:

	IMPORTS.	EXPORTS.
Europe	\$281,091,002	\$901,014,786
North America.	81,287,474	127,125,929
South America.	85,859,245	30,748,846
Asia.	85,381,158	41,561,531
Oceania.	23,365,132	19,979,555
Africa	6,786,017	16,097,959

Societies.

The following recent meetings are noted:

Iowa.—Austin Flint Medical Society, Iowa Falls, July 12 and 13; Iowa Union Medical Society, Cedar Rapids July 13; Southwestern Minnesota Medical Society, Sibley, Iowa, July 14.

Kansas.—Academy of Medicine, Topeka, July 11.

Kentucky.—Lexington and Fayette County Medical Society, Lexington, July 11.

Massachusetts.—Franklin District Medical Society, Greenfield, July 12; Hampden District Medical Society, July 19.

Nebraska.—Elkhorn Valley Medical Society, Norfolk, July 12; South Omaha Medical Society, July 9.

New York.—Jefferson County Medical Society, Watertown, July 9. Oneida County Medical Society, Utica, July 12; Ontario County Medical Society, Canandaigua, July 12; Wayne County Medical Society, Lyons, July 12.

Pennsylvania.—Berks County Medical Society, Reading; Lackawanna Medical Society, July 12; Lycoming Medical Society, Williamsport, July 8; York County Medical Society, York City, July 7.

Vermont.—Union Medical Society, Bennington, July 13.

Wisconsin.—Brainerd Medical Society, Milwaukee, July 13.

Louisville.

EXAMINATIONS.—Secretary McCormack of the State Board of Health held the examination as provided by the recent law regulating the practice of osteopathy, and but one woman presented herself to stand the test. The annual meeting of the State Board of Pharmacy was held in this city last week for the purpose of examining candidates for the practice of pharmacy in the State. Quite a large class took the examinations.

CATTLE.—Since the convention at St. Louis, some time ago, the attention of the State Board of Health has been directed especially to the prevention of the shipment of cattle through the State without proper examination. There is a Government inspector in the city who is doing specially good work and is guarding against the importation and transportation of diseased cattle. There has been some ground for complaint on the part of Indiana and Illinois because of diseased cattle being shipped through Kentucky, and to guard against this an important meeting of the Health authorities, State and local, was held last week to look into the matter and adopt regulations. The following were present: County Judge Gregory; M. K. Allan, Health Officer; J. N. McCormack, Secretary of State Board of Health; Wm. Bailey of the State Board; and Geo. W. Griffiths, B. W. Smock of the County Board and F. C. Eisenman, State Veterinarian. Under rules adopted Dr. Eisenman will examine all cattle which pass through the State and none will escape that are diseased.

Philadelphia.

SURGEONS OF THE KEYSTONE STATE ARE BEING DISCRIMINATED AGAINST.—There are a great many surgeons in the Volunteer Army from Philadelphia and the State at large now at the front. Owing to the laws of certain States the assistant surgeons in the Volunteer Army take the rank and draw the same pay as a captain. In Pennsylvania no such State law prevails, and therefore, assistant surgeons from this State take rank and draw pay as first lieutenants. When it is considered that the Commonwealth of Pennsylvania was one of the first States to furnish its quota of men and gave up its national guard through the ruling of the War Department, it is a source of regret that the medical men are not put upon the same footing as those from other States. It is reported that Governor Hastings has made a test case of and has submitted the facts to the War Department for its decision regarding the matter.

A GLORIOUS FOURTH.—The following casualties are reported

by the different hospitals of the city for July 4: Howard Hospital: Burns 2, contusions 4, gunshot wounds 1. Episcopal Hospital: Burns of the hands, face and neck 11, gunshot wound of finger 1, lacerated wound of finger 1. St. Joseph's Hospital: Burns 3, lacerated wound of finger 1, laceration of hand 1. Presbyterian Hospital: Burns of hands and face 10, lacerated wound of finger 1, dislocation of shoulder from discharge of gun 1. German Hospital: Burns of hands, face and neck 11, gunshot wound of finger 1, lacerated wound of finger 1. Jefferson Hospital: Burns 2, gunshot wound of forearm 1, gunshot wound of hand 1. Medico-chirurgical Hospital: Burns 4, contusions 2. Polyclinic Hospital: Burns 5, lacerated wounds 5, fracture of humerus 1.

HOW THE MORTALITY OF CITIES IS INCREASED.—No better exemplification of the increase in the death rate of cities is needed than to study the enormous increase in the number of cases of cholera infantum as observed during the summer months. For instance, in Philadelphia there have been 720 deaths, of which 185 were caused by cholera infantum alone. During this same period 27 deaths from sunstroke occurred, so that, taking into consideration the different agents which give rise to the increased death rate, we must assign it first to the intense heat which has prevailed, together with rapid fermentation which set up these digestive disturbances. If it were possible to place a medical inspector in each home during the season of intensely hot weather, who could give proper advice regarding the judicious use of sterilized and proper foods, the death rate of any city could be improved. The average person, however, will go on from day to day and give the child uncooked milk, candy, sour potatoes, or probably decayed fruit, and if the child happens to be teething nothing else is needed to bring on an attack of cholera infantum and consequent death. It is hard to convince the average ignorant mother of the dangers attendant upon the administration of improper foods, for the doctor will readily detect that the attention of the patient is lost before he gets through explaining technical terms which she can not comprehend. So the death rate of cities will continue to be high for some time to come. The principal causes of death were: Cholera infantum 185 deaths, tuberculosis 41, inflammation of stomach and bowels 38, marasmus 32, Bright's disease 22, old age 28, heart disease 25, sunstroke 27, cancer 20, apoplexy 17, paralysis 16, dysentery 4, diarrhea 2, convulsions 4. Of the total number it shows an increase of 214 over last year for the same period; 393 were in children under 5 years of age.

INFECTIOUS FEVERS.—This week: diphtheria 11 deaths, 49 cases; scarlet fever 2 deaths, 17 cases; typhoid fever 13 deaths, 51 cases. Last week: diphtheria 10 deaths, 56 cases; scarlet fever no deaths, 26 cases; typhoid fever 10 deaths, 58 cases.

HOT WEATHER EFFECTS.—July 4 the temperature at 5 A.M. was 76 degrees, 8 A.M. 83 degrees, 12 M. 93 degrees and 2:30 P.M. 99 degrees. The humidity was excessive and finally culminated in a hail storm. So intense was the heat that forty-one prostrations were reported, of which seven proved fatal. Children suffered most and the effects are shown by the increased number of deaths from cholera infantum.

PERSONAL.—Dr. Albert E. Roussel of Philadelphia, who holds an important position in the faculty of the Medico-Chirurgical College, sailed last week for Europe, where he will remain for several months. While away he will attend clinics at Vienna, Berlin, London and Paris.

MEDICAL BOARD.—The next meeting of the Medical Board of Pennsylvania will be held in Philadelphia, December 12.

THE PUBLIC SERVICE.

Assignments, etc., of Medical Officers.—To the 1st Army Corps, Major General Brooke, at Chickamauga Park, Ga.: Acting Asst. Surgeon Sidney J. Myers, from Louisville, Ky. To the 2d Army Corps, Major General Graham, at Camp Alger, Va.: Majors Edward Martin and M. C. Wyeth, brigade surgeons, and the following acting assistant surgeons, all from Washington, D. C.: Chas. L. Baker, Howard H. Bailey, Wm. P. Cornell, George L. Hicks, Chas. G. Eicher and John A. McKenna. To the 3d Army Corps, Major General Wade, at Chickamauga Park, Ga.: Major Louis Brechemin, U. S. A., Major R. Emmett Griffin, chief surgeon, and Major Chas. E. Ruth, brigade surgeon. To the 4th Army Corps, Major General Copping, at Tampa, Fla.: Lieut. Bailey K. Ashford, U. S. A., from Ft. St. Philip, La., and the following acting assistant surgeons: Julius A. Eacobar, Richard Wilson, Frank W. Jay, John S. Donaldson, Eugene T. Hancock and Wm. E. West. To the 5th Army Corps, Major General Shafter, at Santiago, Cuba, from Tampa or via Tampa, Fla.: Major John G. Davis, Surgeon 7th Regiment Volunteer Infantry and the following acting assistant surgeons: Maynard G. Burgess, Roger P. Ames, Wm. B. Winn, Eduardo C. Poey, D. T. Lainé, S. M. Gonzalez, all from Tampa, Fla.; J. Stebbins King from Decatur, Ill.; Chas. T.

Newkirk from Washington, D. C.; J. A. Dunwoody from Cripple Creek, Colo.; Allen P. Ebert from Atlanta, Ga., and Chas. L. Le Rœux from Pass Christian, Miss. To the 7th Army Corps, Major General Fitzhugh Lee, at Jacksonville, Fla.: Lieut. James S. Wilson, U. S. A. To the 8th Army Corps, Major General Merritt, Philippines: Major Geo. F. Shiels, brigade surgeon, while Capt. Thomas U. Raymond, U. S. A., has been relieved from duty with the expeditionary force reporting to the commander of the Dept. of California. To the general hospital, Ft. Monroe, Va.: Major Lewis Schooler, chief surgeon from one of the divisions of the 3d Army Corps, and the following acting assistant surgeons: Robert E. Bell, Carl H. Andersen and E. W. Pinkham, all from Washington, D. C.; S. Melville Waterhouse from Ft. Myer, Va.; John S. Fogg from Biddeford, Maine; A. W. Williams from Gainesville, Ga., and Berwick Bruce Lanier from Baltimore, Md. To the general hospital, Ft. Myer, Va.: Acting Asst. Surgeon Joseph J. Curry from Boston, Mass. To the general hospital, Key West, Fla.: Acting Asst. Surgeon Geo. R. Plummer from Washington, D. C. To the Leiter general hospital, Chickamauga Park, Ga.: Acting Asst. Surgeons Joseph C. De Vries and Dudley W. Welch from Washington, D. C.

Major H. H. Arthur, chief surgeon, has been ordered to New York City for the purpose of outfitting a hospital ship.

Assigned.—Lieut. Thos. L. Jenkins, Asst. Surgeon, 8th Massachusetts Infantry, on account of disability.

CHANGE OF ADDRESS.

Allen, C. J., from Peterboro, N. H., to East Barnard, Vt.
Bower, A. L., from 253 S.W. Temple to Progress Bldg., Salt Lake City, Utah.
Benson, J. A., from 103 State St. to 833 Washington Blvd., Chicago.
Bailey, J., from Denver to Florence, Colo.
Brewster, B. H., from Euclid to Hooker, Pa.
Coogrove, T. M., from Anburndale to 837 Monroe St., Toledo, Ohio.
Carpenter, J. W., from Cincinnati, Ohio, to Omena, Mich.
Davidson, S. S., from New Castle to Wampun, Pa.
Dicken, H. W., from Ann Arbor to Romeo, Mich.
Fanner, J. C., from 2022 Portland Ave. to 315 Clinton Ave., Minneapolis, Minn.
Flood, John, from 297 N. State to 237 W. Erie St., Chicago.
Goffe, J. Riddle, from 22 E. 35th St. to New London, Conn.
Haines, W. D., from 583 to 1606 Freeman Ave., Cincinnati, Ohio.
Hays, T. D., from 257 S. Wood St. to 352 Randolph, Chicago.
Hedden, C. H., from Chicago, Ill., to Charles City, Iowa.
Hart, M., from Denver to Grand Lake, Colo.
Kaul, W. M., from Ohio, Ill., to Princeton, Ill.
Lebrecht, J. C., from 14 E. St. to 900 S. 4th St., St. Louis, Mo.
McGahan, C. E., from Aiken, S. C., to 24 W. 57th St., New York.
Mather, E., from Paterson to Jersey City, N. J.
McGready, J. H., from Chicago, Ill., to Independence, Iowa.
McCreery, L. N., from Rocky Ford to University Park, Colo.
Neilson, W. H., from 33 Metropolitan Bldg. to 104 Garfield Ave., Milwaukee, Wis.
Nunstedt, S. H., from Keokuk to Rudd, Iowa.
Oshorne, G., from 161 Michigan St. to 27 N. Clark, Chicago.
Pirosh, B., from 195 W. 13th Pl. to 43 McAllister Pl., Chicago.
Ruth, C. E., from Keokuk, Iowa, to 3d Army Corps, Chickamauga, Ga.
Renn, T. H., from 227 Townsend to Packerton, Ind.
Sternman, W. F., from Louisville, Ky., to Evansville, Ind.
Searles, L. M., from Kansas City, Mo., to Mount Ayr, Iowa.
Somers, L. S., from Philadelphia to Analomink, Pa.
Somers, G. B., from 133 Larkin St. to 1084 Mission, San Francisco, Cal.
Toron, M., from Palace Hotel to 131 N. Clark, Chicago.
Thompson, A. M., from Portland, Maine, to Snowville, N. H.
Underwood, A. M., from Lancaster, Pa., to Grove Beach, Conn.
Wilson, J. B., from Mt. Vernon, Ind., to Canon City, Colo.

LETTERS RECEIVED.

No. 5.

ORIGINAL ARTICLES.

INDOL: ITS RELATION TO PROLONGED SUPPURATION AND LARDACEOUS CHANGE.¹

Presented to the Section on Practice of Medicine at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY F. LEONARD VAUX, M.D., C.M., TRIN.

MEDICAL SUPERINTENDENT ST. LUKE'S GENERAL HOSPITAL,
OTTAWA, CANADA.

In demonstrating the proteids of food as the normal, and therefore the most constant factor in the production of indol, one must not overlook the disintegration of albuminoid tissue. To do so would be a serious omission, for the recognition of an intense indican reaction as a valuable aid in diagnosis, and its general adoption as such by the medical profession must rest largely upon its relation to suppuration and allied degenerative processes, as in the necrosis of syphilis or carcinoma. Indol is set free whenever any of the following processes exist: 1. Suppuration in a closed cavity. 2. Continued suppuration with a free outlet. 3. Ulceration or necrosis of tissue.

As regards the intensity of an indicanuria from either of the first two causes, three factors must be considered: *a*, the length of time in which the purulent fluid has been secreted; *b*, the adaptability of the enclosing surfaces for absorption; *c*, the extent of surface available for absorption.

1. In the case of a sac normally secreting a serous fluid, simple increase in that secretion would not indicate indol formation. And inasmuch as transformation to a typical purulent secretion is a matter of several stages, it is but reasonable to expect at first only a slight indicanuria. And further, when pus is fully formed, the indican reaction will become more and more intense in proportion to the length of time that suppuration persists. This is especially true with regard to the empyemas of childhood, the reports of my examinations in connection with which are here given:

H. G., four ounces pus, urine loaded with indoxyl pot. sulph. (indican); B. I., five ounces pus, urine loaded with indoxyl pot. sulph.; R. J., ten ounces pus, urine loaded with indoxyl pot. sulph.; E. C., eight ounces pus, urine loaded with indoxyl pot. sulph. (five months' duration); K. M., twenty-four ounces pus, urine loaded with indoxyl pot. sulph.; L. I., ten ounces pus, urine loaded with indoxyl pot. sulph.; B. M., eight ounces pus, urine loaded with indoxyl pot. sulph.; F. N., seven ounces pus, urine loaded with indoxyl pot. sulph.; G. B., seven and a half ounces pus, urine loaded with indoxyl pot. sulph.

In addition to the above, I have examined a large number of cases of broncho-pneumonia, lobar pneumonia, and simple pleurisy with effusion; yet never have I found in any of these a heavy deposit of indigo

blue as in empyemata. I have never seen but one single case of pythorax in children in which the presence of a marked indoxyl potassium sulphate reaction, did not accurately foretell a large amount of pus. In the one exception mentioned, the previously sero-purulent fluid had become purulent but a couple of days before operation.

One case in which the accuracy of this test was upheld has fixed itself strongly upon me. B. S., operated upon for empyema, and later the sinus closed very rapidly. Temperature had been normal for some time, but rose suddenly and retention was feared. Before aspirating through the scar, a test case was made of the indoxyl reaction, and upon examination none found. A diagnosis of "non-retention" was then made and proven correct by aspiration as well as later developments, for the classic symptoms of typhoid fever soon appeared and a Widal reaction was obtained.

Indol and empyema of the gall bladder.—I. C., aged 32; history of severe colicky pains in right hypochondrium together with jaundice, fever, chills and general malaise. On palpation a distinct mass could be made out occupying site of gall bladder. A heavy deposit of indigo blue was obtained from the urine and a diagnosis of empyema of the gall bladder was made, the indicanuria ruling out a collection of gall stones. In these cases it will be necessary to have the bowels thoroughly evacuated, else indol formation in the intestine may be excessive and misleading. Such a case has come under my notice.

Indol and abscess of the liver.—I. B.; all physical signs of liver abscess. Indoxyl reaction intense. Upon operation multiple abscesses found and large amount of pus evacuated.

Indol and perinephritic abscess.—*a*. M. S., perinephritic abscess rupturing into pleural cavity; large amount of pus evacuated; indoxyl reaction heavy. *b*. T. C., supposed perinephritic abscess; there being temperature and a tumor. Indoxyl examination showed only a trifling increase over normal, such as would result from digestive disorders, but not such as would come from pus. The diagnosis of renal calculus being therefore made was found upon operation to be the correct one. *c*. I. B., pyonephrosis and perinephritic abscess; very marked indicanuria.

Indol and bronchiectasis.—*a*. E. F.; typical physical signs; very foul odor of breath; indoxyl reaction intense. Upon aspiration of cavity two and a half ounces of pus were withdrawn. *b*. S. B.; bronchiectatic cavity; odor of breath intensely fetid; purulent matter coughed up; indoxyl pot. sulph. heavy.

Indol and subdiaphragmatic abscess.—F. T.; high fever, 104 to 105 degrees F.; great pain over diaphragm in breathing, together with extreme tenderness on palpation. There being no indicanuria a subdiaphragmatic abscess was excluded. No pus was found upon aspiration, and the following day the temperature became normal.

NOTE.—I am indebted to Dr. A. G. Gerster, Chief of the Surgical Staff, Mt. Sinai Hospital, New York, for permission to use the above statistics.

2. Continued suppuration with a free outlet does not present any very distinguishing feature. In time, however, as solid tissue, such as bone, becomes worn away the elimination of indol is most intense.

In both forms of suppuration the production of indol will be great, but the amount finally eliminated in the urine will depend largely upon the characteristics and size of the surrounding tissue. Thus, in a

¹ This paper was presented under a nom de plume and was awarded the gold medal offered by Trinity Medical College Alumni Association, Toronto. The judges were Dr. Wyatt Johnson, Dr. Adams and Dr. Rutlan, all of Montreal.

case of suppurative peritonitis, where pus is free in the abdominal cavity, the indicanuria will be inky in its intensity and in a comparatively short time, while the same amount of pus in the pleural cavity would only produce a similar degree of indicanuria in from six to ten weeks, or perhaps not even then. Assuming, for argument, a case of chronic Pott's disease with marked suppuration; by what chemic or physiologic means is indol formed and eliminated as indoxyl? The answer is made doubly difficult by our lack of knowledge as to the arrangements of atoms in the primary albuminoid molecule, a point which even the most modern researches have failed to elucidate. E. and H. Salkowsky, who have given so much time to the study of indol, have paid special attention to this, arriving at the following conclusions: "That in the putrefaction of albumin indol is not immediately liberated from the proteid molecule in a free condition, but that an intermediate product is formed, which is gradually decomposed by the further action of bacteria. This intermediate product is not, however, peptone, the quantity of which throughout the process of preparation is small and in the later stages seems entirely to disappear." Baumann, who first advanced the theory, held that the intermediate product was soluble in a mixture of alcohol and ether. From this substance (which is not biuret) we may reasonably assume that tyrosin is formed, it being the mother substance of indol. But we still find ourselves confronted with the questions, what is the antecedent of tyrosin; and, where does tyrosin become changed into indol? To even approximate an answer it is essential to consider the relation existing between the liver and tissue metabolism. Of necessity, our knowledge in this respect will be limited, for there comes a point when the processes of living tissue can not be reproduced in the test tube or crucible.

Nevertheless, from the products of metabolism we may learn much about the source. Urea and leucin, as allied products, may be of some value in these investigations. Since the synthetic production of urea it has been closely studied and many theories formed as to the site of its origin. Being such an important urinary constituent it was first believed to be a renal product, next the muscular tissues were supposed to be its seat, owing to its increase after exercise, and only lately has it practically been accepted as a product of the liver. When, however, we speak of the liver as the source of an albuminoid product, we really mean that this substance or its antecedent is deposited there by the blood, undergoes certain reducing processes and is again set free to be eliminated.

Consequently we presuppose a mother substance, bearing to urea, leucin and tyrosin the same relation that indol does to indoxyl, or indican to indigo blue; and like indoxyl circulating in the blood, probably in direct connection with the leucocytes. As a sequel to this hypothesis it must be assumed that the liver, by its reducing power, normally separates tyrosin from its unknown antecedent and finally indol is set free by a continuation of the same process. Most important as substantiating this view, are the researches of M. Nepveau and M. Villiard, distinguished French scientists of Marseilles and Paris respectively, who have shown that from the maceration liquid of certain pathologic specimens, indigo blue may be precipitated.

Nepveau first made his observations on a very limited number of cases, and after noting the results in the *Marseilles Médicale*, turned over the subject to

Villiard for further investigation. The results obtained I append, together with his notes:

"Nepveau has demonstrated that by examination of the alcoholic maceration liquid of organs, one may find indol or indican a considerable time after death; in one case, in the liquid from a subject after several months, the cause of death being hematuric biliary fever. The liquid in this case has been changed four times. The alcoholic, maceration liquid of other organs than the liver did not give the reaction. I have been able by nitro-prusside of soda and 2 minims H_2SO_4 , to demonstrate indol in the tumors of different cases. One should allow the liquid to remain twenty-four hours, then at the bottom may be seen an intense blue coloration. The liquid of maceration has been absolute alcohol, and we have obtained the following results:

1. Liver. Biliary hematuric fever, very intense (Nepveau).
2. Liver. Pulmonary tuberculosis, very intense.
3. Liver. Death from trauma, very feeble,
4. Liver. Uremia, very feeble.
5. Liver. Uremia, very feeble.
6. Liver. Pylephlebitis, very intense.
7. Liver. Broncho-pneumonia and grippe, feeble.
8. Liver. Fatty degeneration, intense.
9. Liver. Atrophic cirrhosis, *nil*.
10. Liver. Cholera, intense.
11. Liver. Beri beri, feeble (Nepveau).
12. Kidney. Uremia, intense.
13. Kidney. Uremia, *nil*.
14. Kidney. Biliary hematuric fever, *nil*.
15. Spleen. Biliary hematuric fever, *nil*.
16. Spleen. Broncho-pneumonia and grippe, *nil*."

"One may see by these remarks, that indol has been found in a number of cases. These researches are, however, on entirely too small a number of cases to enable us to arrive at precise facts as to the constant presence of indol in each pathologic organ. It will therefore always be necessary, in order to obtain an exact result, to know in each case: 1, the exact size and weight of the anatomic specimen; 2, the quality and strength of the liquid used; 3, the number of macerations."

"In examination of the maceration liquid of four successive macerations of numbers two and six, we have found in each maceration a diminution of the intensity. The reactions from kidneys, spleen and lungs are not constant, and will not permit of conclusions. But it will be admitted that the liver gave a pretty constant reaction, viz.: a characteristic indigo blue precipitate."

"The solution used in oxidizing the maceration liquid is as follows: Place in a test tube 5 c.c. of the alcoholic liquid of maceration (of a carcinoma of the liver, for example), add to it nitro-prusside of soda 5 parts, and in addition 30 parts of a solution of caustic soda, some drops of crystallized acetic acid and 4 drops concentrated sulphuric acid; make up with water to 100. There will be immediately produced on contact of the two solutions and the liquid, the coloration of indican, and very strongly so in twenty-four to forty-eight hours."

Not having as yet made use of the above solution I can not state its powers of oxidation, but should judge them to be quite marked.

The results quoted above, while apparently most important and convincing, must be confirmed by pathologists from all sections of the country. I myself have not been as yet fortunate in securing pathologic specimens from cases of carcinoma or prolonged suppuration, but hope before long to be able to report results of such examinations.

We may assume, then:

1. That suppuration, or rapid degeneration of tissue, causes an increased amount of indol to be deposited in the liver.

2. That in such cases there will also be an increased elimination of indican.

3. That postmortem we may, by simple extraction with absolute alcohol, take from the liver the excess deposit as its oxidation product, indigo blue.

I lay particular stress on these points, bearing as they do upon the question of the nature of that peculiar tissue change known as lardaceous degeneration, and next to be discussed.

Indol in relation to lardaceous change.—It is safe to say that the tissue metamorphosis commonly known as waxy, amyloid or lardaceous degeneration, is today almost as great a mystery to pathologists as in the earlier years of the century, when Virchow wrote about it. It is, however, worthy of note that a revival of interest in this subject is being manifested, both in Europe and our own continent; much careful work being done in government clinics and private laboratories. In Europe Virchow, Krakow, Czerny, and in England Howship Dickinson, are conducting elaborate investigations, while in Canada and the United States, private enterprise is being enlisted. Three factors render research difficult:

1. It is not always possible to say definitely during life, that lardaceous changes are actually going on, for even when there is good reason for believing that the kidneys may be involved, waxy casts may be absent from the urine.

2. The cessation with death of liver metabolism leaves us with but little to work upon.

3. Even when, with difficulty, the lardaceous material has been isolated from the liver, it responds to so few chemic tests as to give small chance for experiment.

As an offset to these disadvantages, it may be said that the etiology has been limited to two causes: degeneration of tissue and suppuration; whether these occur from bacterial activity, tuberculosis, syphilis or malignant disease.

What, then, has been the result of a century of work? This can best be answered by the following statements:

1. Previous to this century, the conditions under discussion had been noted, and the term "lardaceous" applied.

2. In the early years of the century great attention was paid to this condition by the Edinburgh school, and by them the term "waxy" applied to it.

3. In 1853, Virchow discovered the peculiar bright blue reaction obtained from the corpora amylacea upon the application of iodine and H_2SO_4 . From its similarity to the starch reaction with the same reagents, he named it "amyloid."

4. Later Kekule, Friedrich, Schmidt and others demonstrated its nitrogenous composition and proved it to be closely allied to the albuminoids, and not starchy.

5. Kühne submitted degenerated organs to gastric digestion for a long period, finally succeeded in isolating thus the lardaceous material, and confirmed the views of Kekule.

6. Dickinson, noting that in long continued suppuration the lardaceous changes were more intense when free outlet was afforded for the pus, advanced the theory that in the purulent discharge alkaline salts

were carried away, the resulting fibrin being the morbid material.

7. Ehrlich found that aniline dyes, notably alizarin blue and indo-phenol blue, were decolorized by the normal tissue of a lardaceous liver, but unaffected by the degenerated portions.

8. Czerny claimed that the white blood cells contain the precursor of the lardaceous material.

9. Krakow and others have undertaken experimental researches by inducing suppuration in animals, that the lardaceous changes may be studied in various stages.

Many more observations and experiments might be quoted, but those given outline fairly the trend of thought. Before proceeding to further discuss the nature of this morbid material, it might well be noted, that the theory of an absolute retrograde metamorphosis, as opposed to an infiltration of new material, is no longer held. On the other hand, it is freely acknowledged that whatever material be brought to and deposited in the liver, it there undergoes an almost complete transformation by the action of the liver protoplasm. Thus the question as to whether lardacein is entirely a product of degenerated cell action, or entirely an infiltration, need not longer be discussed, for undoubtedly it exists as a result of both causes, the essential factor in its formation, its precursor, that to which the color reactions are due, being deposited by the blood; while on the other hand, the nitrogenous element, that which yields tyrosin and leucin, is due to degenerated cell action. Thoma says: "It is quite possible to conceive that a preliminary stage may exist, in which the amyloid antecedent circulates in the blood, finally to pass out into the tissues and be converted into amyloid by the action of the cells." Ziegler also believes that "amyloid-forming" material pre-exists, and its deposit induced by the lowered vitality of the whole body, is due to suppuration or dyscrasia. So too Czerny, whose researches will be referred to later, believes that the leucocytes convey the amyloid precursor.

Granting that the primary and most important factor is the deposit in the tissues by the blood of an "amyloid-forming material," what is the nature of this mysterious substance? I would here with much hesitation advance the theory that this deposit is but a derivative of indol, which retains through all changes its power of easy oxidation into indigo red and blue.

We may now note the chemic properties of lardaceous material. Lardacein has the chemic formula $C_{53.6} H_7 N_{15} S$ and O 24.4 per cent., being thus closely allied to albumin and giving the xanthoproteid reaction, as also that of Millon. It is dissolved out with difficulty, and only by the concentrated acids and alkalis, being then converted into an acid or alkali albuminate. On boiling with acids it yields leucin and tyrosin.

The following color reactions can be obtained: Reddish-brown with iodine, violet or blue by iodine plus H_2SO_4 , red by methyl anilin, red by amber green. Of all the above color tests, those with iodine are the most characteristic and important, being constant and typical. Following out the hypothesis advanced with regard to the relation between indol and the primary deposit, we must look upon the mahogany red as nothing more nor less than the liberation of indigo red from the tissues, through the powerful oxidizing powers of iodine: further oxidation to indigo blue

being afforded by the concentrated sulphuric acid used in the second stage of the reaction.

In this connection the well-known blue reaction obtained from albumin in the presence of strong HCl and oxygen, is of interest. Here too we may reasonably assume that the action of the HCl is to set free from the albumin a derivative of indol, from which in turn the oxidizing power of the atmosphere soon liberates indigo blue. Occasionally also when using Heller's test, in urines loaded with albumin, the blue coloration will appear. Halliburton first called attention to the fact, as a possible source of error in testing for indican. As a matter of fact, it will be found that such a specimen is actually loaded with indican, the fuming HNO_3 playing the same rôle as the combined action of the weaker solutions, and effecting a double oxidation, indol into indoxyl potassium sulphate, and this into indigo blue.

But striking as the color reactions of lardaceous degeneration may be, and while to me they form the strongest evidence in support of the theory advanced, other proof must be adduced, before such a connection can be accepted as even possible. These other points of similarity are here arranged in parallel columns:

<i>The Lardaceous Material.</i>	<i>(The derivative of) Indol.</i>
1. Occurs in chronic suppurations.	A marked and persistent elimination of indol is seen in such cases.
2. Yields tyrosin.	Is a product of tyrosin.
3. Is deficient in potassium.	Shows a marked affinity for potassium.
4. Seat of election is the liver.	Indol is deposited in the liver in suppuration.
5. Its primary factor is deposited by the blood.	Circulates in the blood and is there oxidized.
6. Gives red or blue color change with oxidizing agents.	With oxidizing agents yields indigo red and blue.

1. About this little need be said, it being acknowledged by all writers that in chronic suppurations, or other disintegrations of tissue, indol is markedly and constantly eliminated, while the very same processes are being recognized as the only factors in lardaceous change. In other words, there is etiologic unity as regards the primary factor of lardaceous material, and the indolic pigments excreted in the urine.

2. At present not much can be said about the relation of tyrosin to these changes. It may be that in this production of leucin and tyrosin from lardacein, we have a hint of certain important proteolytic functions; but the chances are that the presence of these two rare end-products can be accounted for by the destruction of the nitrogenous element in lardaceous change, the portion produced by degenerate cell action.

3. As regards the deficiency of potassium, it must be admitted that unusual attention has been directed toward this condition. Dickinson and Marcet make many observations on this point, the former going so far as even to base a new theory upon it. That there is a marked difference in the amount of potassium is best shown by the statistics Dickinson himself gives. In seven healthy livers potassium = .209. In seven lardaceous livers potassium = .169. Noting also that in cases of continued suppuration where free outlet for the pus was afforded, the resulting lardaceous changes were more extensive, he became convinced that the fibrin resulting from this loss of alkalinity, being no longer held in suspension, was deposited in the affected organs. There is no need of discussion of this theory, Dickinson himself having abandoned

it. But may there not be another explanation of a fact which has been dwelt upon by nearly all modern writers on the subject? It seems possible that in the affinity of indol to potassium, we have an attempt of nature to repair this loss. While we have not as yet discovered an exact relation between lardaceous material and the indigo group, yet already enough striking similarities have presented themselves to warrant us looking closely into the matter; and of these, this deficiency in potassium, which was so marked as to have led Dickinson into advancing a new theory, may well claim once more our attention, and demand our careful investigation.

4. While it is true that, given the proper etiologic facts, lardaceous change will go on wherever there is blood supply, nevertheless it is a well known fact that the liver contains in each case by far the greater amount of this morbid material; so much so, in fact, that this organ is the one usually employed in experiments. Statistics to this effect are given by Kyber, Virchow, Dickinson and others, while the fact is in accordance with the law, "Lardaceous infiltration of organs is in direct proportion to their blood supply;" still, there is another and more important reason. I refer to the proteolytic function of the liver.

The power of proteolysis is being dwelt upon more and more by physiologists, and certainly it is of the greatest importance to all students of internal medicine. In the various changes which indol undergoes it undoubtedly plays a large part. Normally the process is probably as follows: Indol having been produced ultimately from the decomposition of proteid material, is absorbed and carried into the portal circulation. Here, under the combined oxidizing, reducing power of the blood and liver cells, it becomes indoxyl, a portion of which, either as such or in an altered form, remains stored away, as it were, in the liver. That which goes on again into the blood stream is eliminated in the feces and urine. The proof that indoxyl or its derivative remains in the liver, may be found in the researches of Nepveau and Villiard, quoted above, by which they obtained indigo blue by simple maceration of livers. These livers were from the very type of case which during life would show a marked indicanuria.

Accepting then this view, as representing the normal condition of things at the commencement of a suppurative process, it follows that, later on in the course of the dyscrasia, there will result a generally lowered vitality, affecting ultimately all finer natural processes, and producing in consequence diminished proteolytic powers in the liver. Hence there will be inability to properly oxidize or reduce indol, and pass the resulting product in part out into the general circulation. Thus there will remain in the liver an unusually large amount of an improperly reduced and indigo-forming substance, constantly increasing, and to which there will be added, as a further result of the impaired proteolytic and eliminative power, nitrogenous waste and degenerate cell products. From the union of all these there would result, in course of time, that which we know as lardaceous material.

But most important of all are the characteristic color reactions of lardaceous material. We know that the application of a watery and entirely colorless solution of iodine and potassium iodide to lardaceous organs, produces at once in the degenerate portions a mahogany red tint which has never yet been satisfactorily accounted for, but bears the closest resem-

blance to indigo red. The fact that this pigment, rather than indigo blue, should appear primarily, is of no account, inasmuch as both have the same chemic composition, there being merely a different arrangement of the molecules. The same phenomenon occasionally occurs in urine analysis, indigo red being thrown down and later under atmospheric oxidation becoming indigo blue.

Directly bearing on this question are the following classic observations of Schunck:

"1. Two distinct periods may be observed in the decomposition of indican: during the first the indigo blue is the chief product, during the second red and brown coloring matters with but little indigo blue are seen. 2. Let a watery solution of indican be boiled for some time and it then yields by decomposition not a trace of indigo blue, but only indigo red. 3. If it be boiled as before, but with the addition of alkalis, it then gives neither indigo blue nor indigo red, but only a brown resinous matter, indiretin."

The second color change, that resulting from the application of strong H_2SO_4 to the portions already stained red, is the appearance of a dark violet blue, occasionally a blue black, and very rarely a bright blue. Again the parallel is striking; the oxidizing power of the concentrated H_2SO_4 altering the molecular arrangement and converting indigo red into indigo blue. Dickinson, it is true, has explained this reaction upon another basis, that of a combination between the sulphuric acid and iodid of potassium, resulting in a precipitation of iodine which blackens the tissues. But it is to be observed that although this view was first advanced in his "Treatise on Albuminuria," published in 1881, it has not as yet met with general acceptance, nor does it help in any way to explain the previous color reaction—mahogany red.

The effect of strong alkalies must be noted here. To obtain lardaceous material for study, an affected organ is treated with caustic potash, the infiltrated portion is dissolved out and a white, flaky precipitate obtained by subsequent acidulation. This precipitate will not respond to iodine or H_2SO_4 in the usual manner; but gives only a fawn color as does a similar precipitate from a healthy liver (Dickinson). So, too, if liq. potassæ be poured over lardaceous material *in situ*, before ever that identical portion has been subjected to reagents, it loses then and there its power of giving the iodine reaction. Hence the liquor potassæ, not the acid, affects it.

Now note the effect of boiling a watery solution of indican with alkalies (liq. potassæ) as described by Schunck, *vide supra*. Then compare the reaction there obtained with that just described. In both cases we see the power of yielding an indigo red tint destroyed. In short, another indigo-producing substance has been disorganized by liquor potassæ.

The relation of indigo blue to indigo white is of great interest. A solution of indigo white or indigogen when exposed to the air gradually combines with oxygen and deposits indigo blue. On the other hand, indigo blue, though strongly resisting all chemic agents, may be reduced to indigo white by fermentation. Concentrated sulphuric acid dissolves indigo blue without destroying its color, but strong liquor potassæ completely destroys its blue. In the reduction from blue to white one atom of H is gained. After liquor potassæ has been added and the blue color destroyed the tint can not be restored. But if a reducing agent is present and an acid be added, a grayish-white sub-

stance is deposited in flakes, to which the name indigogen or indigo white is applied (Schunck).

In this experiment, taken in conjunction with our previous observations, do we not find confirmation of the hypothesis advanced, viz., that a member of the indigo group is an active factor in lardaceous change? Thus, the flaky white material dissolved from degenerate organs and finally precipitated as such, bears a strong resemblance to the indigogen or indigo white just referred to. But where is the reducing agent which it has been stated is necessary to complete the process? This may be found in the action of the liver protoplasm itself, a reducing agent of no mean power, and which in spite of advanced degeneration must necessarily retain some power; for we know that a solution of alizarin blue or indo-phenol blue (an indigo derivative) is decolorized by living hepatic protoplasm, the liver cells possessing an inherent power of reduction either by themselves or through the agency of certain ferments. This is well expressed by Gamgees: "The forces peculiar to protoplasm, unknown to us but acting similarly to heat, increase the intramolecular movements of the atoms in such a way that a loosening or splitting of the molecule occurs and an aggregation of the oxygen is made possible—primary oxidation." We term this force "the proteolytic power of the liver," and Hunter has pointed out that its variations may in part be recognized by the variations of urinary pigments.

In contradistinction to the reducing power of alkalies as liq. potassæ, may be seen the oxidizing power of certain acids, as HCl, by the following observation of Dickinson: "While the liq. potassæ added to lardaceous material prevents color reagents, HCl in weak solution increases the power of the lardaceous material to respond to iodine, the resulting tint being a deeper and more durable red." What is this but the increased liberation of indigo red due to oxidation by HCl as seen ordinarily in the test tube?

Finally, the experiments of Czerny, to which reference has been made, are of the greatest practical importance. Producing lardaceous change in the organs of animals by inducing suppuration, he was led to submit the pus cells to the combined action of iodine and H_2SO_4 . To his surprise the two reactions of lardaceous tissue were reproduced. Further experiments showed also that in the leucocytes of the blood similar reactions might be obtained. In his own words: "The appearance in the pus of cells giving the characteristic amyloid reaction, the discovery in the blood of the cells and the appearance later of amyloid degeneration in the organs are facts which speak for one thing, viz., that through the leucocytes is carried a substance which must be regarded, not as a glycogen but as a forerunner of amyloid. This being my view it becomes obligatory to answer the question: Is the amyloid substance itself prepared in the blood and from it deposited in the tissues?"

The acceptance of this view will go a long way toward proving that an indigo-producing substance and not a mere tissue characteristic is the basis of the well-known color changes. For we know that indoxyl circulates in the blood, is produced in excess in suppuration and may be extracted from the liver (as indigo blue), where death has resulted from the cause. It remains but to demonstrate that the red and blue colorations of the so-called amyloid reaction are indigo red and indigo blue and nothing else. But to prove this beyond cavil will require much

time and numberless experiments. Our researches, however, will be aided by knowing that amyloid changes may be produced experimentally in animals in from four to six months.

The latest information upon the whole subject of indol production is from the able pen of Dr. C. A. Herter. Two new facts are given: one that there is in the blood that which will very quickly oxidize or reduce indol into some other form; the other that in cases of chronic indol poisoning the chief changes found were in the liver, the capillaries of the lobules being much congested and the liver cells the seat of pigmentation.

Do not these observations bear out in part the theory already advanced in this article?

SURGERY OF THE LUNG.

The Oration in Surgery Delivered at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Col., June 7-10, 1898.

BY J. B. MURPHY, M.D.

CHICAGO, ILL.

(Continued from page 165.)

SURGERY.

We will first consider accidents to and operations on the lungs. Then we will consider the diseases of the lungs and the applications of surgical procedures to them. We will also consider the general pathologic and surgical principles underlying operative procedures on the lung. I propose the following proposition without argument: The important diseases of the lungs are all due to foreign bodies, either mechanical or bacterial. Therefore viewing the question from this etiologic standpoint, in the present state of medical science operative procedures should be habitually performed. The general principles are: 1. To place the tissue in such condition as to increase resistance to infection. 2. To remove: *a*, foreign bodies; *b*, the products of infection, which in turn are foci for further infection; *c*, tissue injured beyond repair, which constitutes foyers of new infection.

Lung operations divide themselves into two classes: 1. Those that do not perforate the visceral pleura. That class of operations aims to convert the hard-walled cavity into a collapsible one. The necessity for these operations arises from the physics of the lung. The indication is collapse, and is met by: *a*, an opening in the soft parts, allowing air to enter; *b*, removal of bony parts, allowing air to enter and the wall to collapse; *c*, collapsing the lung by forcible injection of gas or liquid into the pleural cavity. 2. Those that perforate the visceral pleura. They are divided into: *a*, those that simply perforate the lung—pneumotomy; *b*, those that remove all or some portion of a lung—pneumectomy.

What are the pathologic conditions, on the one hand, requiring collapse, on the other limiting the advisability of operative procedure to collapse? *a*, empyema; *b*, tuberculosis that is moderately advanced—too far advanced for pneumectomy.

In considering these subjects several questions arise:

1. Is the lung, situated in its bone-bound cavity, accessible to surgical manipulation? *a*, What are the difficulties and dangers encountered in entering this cavity? *b*, To what extent may this wall be removed and replaced and what manipulation is permissible within the chest?

2. What is the effect of opening the pleura—of pneumothorax? *a*, Immediate—1, with adhesions; 2, without adhesions. *b*, secondary. How can its dangers be avoided or lessened?

3. Can the lung be incised? In pneumotomy what are the dangers and limitations? They are: *a*, hemorrhage; *b*, pneumothorax—1, from opening in chest; 2, from opening the bronchi; *c*, inflammation—1, pleuritis (of same and opposite side); 2, pneumonia (traumatic); *d*, sepsis.

4. What are the pathologic conditions of the lung requiring incision—pneumotomy? *a*, hernia; *b*, injuries (infected); *c*, abscesses; *d*, bronchiectasis; *e*, gangrene; *f*, foreign bodies; *g*, tubercular cavities; *h*, hydatids; *i*, actinomycosis.

5. Can the lung be excised? In pneumectomy what are the dangers and limitations? They are: Immediate—*a*, hemorrhage; *b*, pneumothorax; *c*, dyspnea (causes and relief). Secondary—*a*, shock; *b*, dyspnea; *c*, hemorrhage; *d*, sepsis; *e*, pleuritis and pneumonia on opposite side. Best method of treating stump: Extra-thoracic, intra-thoracic, drainage or closure. Pathologic histology of repair of stump: Artery, vein, bronchus.

6. How is the chest filled after excision? What are the pathologic conditions in which excision is desirable or required? 1, Neoplasms of chest wall involving lung; 2, circumscribed tuberculosis.

7. Can the lung be defunctionalized? How may this be accomplished artificially and quiescence maintained? 1, By injections into the pleural cavity; 2, by resection of the ribs, which allows the chest wall to collapse; 3, thoracotomy, with separation of pleural adhesions and compression of lung. What are the technical difficulties of intra-pleural injections? *a*, Adhesions; *b*, consolidations. What are its technical dangers? *a*, Air embolism; *b*, sub-pleural emphysema; *c*, pulmonary emphysema; *d*, dyspnea; *e*, sepsis—1, from without; 2, from within (1, tubercular foci, 2, septic foci). How can we determine that the injected material is passing into the pleural cavity and not into the lung tissue or bronchus? What is the most desirable material to use for injection? What are the effects of this pulmonary quiescence on the healthy lung—on diseased lung—particularly in tuberculosis? How long must a lung remain functionless that the process of repair in tuberculosis may be complete? Are pleuritic effusions beneficial or prejudicial to the repair of tuberculosis of the lung?

From the dawn of the history of medicine we find recorded cases of accidental penetrations of the chest by sharp or pointed bodies, as stakes, lances, sabres, bullets, forks, etc. The results of these accidents were hemorrhage, pneumothorax and pulmonary hernia, etc. An analysis shows that many of the cases recovered without surgical interference, and that a smaller number did not even present symptoms of a grave character. With these cases as guides and inducements for surgical exploration the surgeon was slow to act on the evidence which they presented. Large portions of the chest wall have been torn away accidentally and removed for tumors of the breast without opening the pleural cavity, and no special danger was attributed to the procedures. Incisions were made between the ribs for the relief of pathologic conditions from the time of Hippocrates, still it remained for Estlander, Schede and Delagénère to popularize the free opening and removal of a considerable portion of the bony parietes. They have shown that over one-half of the costal framework of one side of the chest may be removed without any great danger. But in their operations they had present a pathologic condition of the pleura, which formed practically a secondary inner chest wall for the respiratory apparatus. As a corollary to their procedure we find recorded a number of cases of removal of the chest wall for neoplasm when there was no such secondary thoracic wall to protect the lung; the latter collapsed and the cavity filled with air. The extent to which the chest wall has been removed in these procedures can be estimated from the operations of Kolaczek,³² Liesrink,³³ Sedillot, in the pre-antiseptic period, resected the rib, pleura and part of an adherent lung successfully; since then Mass,³⁴ Kroenlein, Mil-

³² Arch. für Klin. Chir., b. 24.

³³ Ibid. b. 26.

³⁴ Verhand. des Chir. Cong., 1885.

ler and many others have opened the pleura and removed lung tissue successfully in operations on the chest wall. Cairo³⁵ collected twenty-seven cases and found that five died immediately after the operation and three somewhat later. He included cases in the pre-antiseptic period. In the later cases not a patient succumbed as an immediate result of the operation, so that the removal of the chest wall with opening of the pleural cavity is today a recognized surgical procedure. Weinlechner's case is an exception to the above; he removed a large myxochondroma of the rib, resected three ribs and left an opening in the chest wall as large as the palm of the hand; he was unable to secure a flap sufficient to cover the opening; tampon of gauze; the patient died of a septic pleuritis in twenty-four hours. Kroenlein³⁶ in 1883 removed a large portion of the chest for sarcoma of the rib which involved the pleura; in 1887 he removed from the same patient a recurrent growth involving the chest wall, pleura and lung; the latter was separated and the cavity was drained. The patient lived for seven years after the primary operation.

What are the dangers of operation on the chest wall? They are: Shock, hemorrhage, pneumothorax and sepsis.

Shock.—The shock from injuries and operations on the chest wall, without involvement of the internal viscera or the opening of the pleural cavity, is usually very slight, as may be estimated from the extensive thoracoplastic operations which are now in vogue, and will therefore receive no special consideration.

Hemorrhage.—Injuries during operation to the internal mammary artery are not likely to occur, as operations on the lung and pleural cavity do not usually extend so close to the sternum. Accidents with fatal hemorrhage from this artery have not been frequent. Situated as it is on the inner side of the chest wall (see Fig. 9) hemorrhages from it, except when the opening is large, are mostly internal and not easy of recognition. However, the regularity of its course in the upper part of the chest close to the sternum enables the surgeon to estimate with considerable exactness the probability of its involvement in a particular injury. In eleven cases reported by Tourdes, six died; all five cases recorded in the history of the American war terminated fatally. (Paget.) The diagnosis should be based on the location and direction of the penetration, the general signs of hemorrhage, accumulating fluid in the pleural cavity with collapse of the lung and occasional external hemorrhage from the wound or hemoptysis. Where internal mammary hemorrhage is seriously suspected the surgeon should have the courage of his convictions, enlarge the wound to the pleura and if necessary resect the cartilage, then the bleeding points may be recognized and ligated. Another method suggested is the placing of a ligature upon the proximal side of the injury in the second intercostal space within a quarter of an inch of the sternum. Ligation in loco is preferable, as hemorrhage from the vein, as well as the artery, is grave. We should have no more hesitancy in opening the chest wall for hemorrhage from its arteries or from the lung than we should in opening the abdominal wall under the same conditions, as with a hemothorax already present the lung is collapsed and the effect of a pneumothorax is of little importance. The question of hemorrhage from

the intercostal arteries is of great importance to the surgeon. Fatal hemorrhage from an intercostal artery has followed paracentesis and simple thoracotomy for the relief of a pleuritic effusion, and many fatalities are reported from injuries to these vessels. Paget reports twenty-three cases, eighteen of which terminated in death; fourteen of these were operated, with eleven deaths, showing what a great mortality occurs from an injury to such a small artery. It should be borne in mind that deaths did not follow extensive operations on the chest wall involving these arteries, as in the Estlander and Schede operation, as the hemorrhage in these was easily controlled, but that they followed small incised, punctured and penetrated wounds; the most dangerous condition is a splitting of an artery. The hemorrhage presents the same symptoms which guide us in the recognition of hemorrhage from the internal mammary. The indications for treatment are compression and ligation. I mention compression first in order to emphasize that it should never be relied on, either as compression from within by a plug attached to a strong silk ligature or as pressure from without. Ligature including the rib on either side of the wound is also to be deprecated. The intercostal wound should be enlarged and the bleeding point detected by the hot, pulsating stream against the end of the finger; better still, a subperiosteal resection of the rib should be made, which insures an inspection of the field and accurate localization and ligation of the bleeding points. It should be a surgical law and applicable here that when a surgeon is called to a primary or secondary hemorrhage his operation should be as radical as is necessary for the absolute control of the hemorrhage; he must not temporize, as these patients give him only one opportunity; if this is not taken advantage of they are lost.

Pneumothorax may be classed as traumatic, idiopathic (internal pathologic) and therapeutic. The apprehension of this condition has been the greatest barrier to the surgery of the chest, and still it has been one of the most common sequences to traumatism of the chest wall, as pneumothorax with or without emphysema following fracture of the rib. We ask, what are its dangers? Is the admission of air into the pleural cavity in itself a dangerous occurrence? If so, why? Is the danger due, 1, to the shock to the pleura from the admission of the air or to its absorption; 2, to compression of the lung and impairment of the respiratory exchange of gases; 3, to effect upon the pneumogastric filaments by the sudden contraction of the lung tissue; 4, to displacement of the mediastinal organs, constricting and affecting the cardiac outlets; 5, to displacement of the mediastinum, lessening the power of expansion of the other lung; 6, to increase of tension in the circulation by collapse and emptying of such a large quantity of blood from the lung into the general circulation. Different observers attribute the unpleasant effects produced by pneumothorax to the above-mentioned causes. That there is little shock or discomfort produced by the admission of air into the pleural cavity has been shown by numerous accidents to the chest, experiments and operations extending from the time of Hippocrates to the present day. The infrequency of unpleasant symptoms from traumatic pneumothorax may be estimated from the reports in the surgical history of the American Civil War; in 11,540 chest wounds, unpleasant complications from

³⁵ Deutsch. Med. Woch., 1893, Bd. lii.

³⁶ Berl. Klin. Woch., 1884, b. xxi, site v.

this cause were recorded in less than half a dozen (Paget). In twenty years' experience in emergency surgery of the large hospitals I have observed traumatic pneumothorax as a cause of unpleasant symptoms in but two cases; in both of these the wounds were small and situated in large bronchi near the hilum of the lung. In my recent compressions of the lung by injections with nitrogen gas, in my first case 120 cubic inches having been used, there was only a temporary dyspnea produced. The patient was up from the table within five minutes and refused to go to bed. In my second case I injected 200 cubic inches; it produced quickened respiration, a feeling of constriction in the chest, slight dyspnea and tickling in the throat. In the normal conditions of the pulmonary organs with a perfectly developed mediastinal septum the opening of the chest for the admission of air is not a grave occurrence, although pneumothorax is a more serious condition than emphysema. There are circumstances which make pneumothorax dangerous to life, as when the air is admitted into the pleural cavity through a valvular opening either from within or without; in which condition it may attain a considerable degree of pressure. In perforating wounds of the chest, even when the external wall and a bronchus are opened, pneumothorax is not a necessary sequence, as the cohesion of the pleurae (West, Brousseau) as well as pathologic adhesions prevent its formation. This cohesion must be stronger than the contractile power of the lung, which is equivalent to about 7 mm. of mercury or $3\frac{1}{2}$ inches of water. In my experiments and in operations in which no pathologic adhesions have existed, I have not observed in a single instance that the lung remained in apposition with the chest wall when the upper air passages were free. I am convinced from a careful observation and demonstration of this point in experiments that the pleurae do not remain in contact when air is admitted into the pleural cavity, even through pin-hole openings. With each inspiratory act the lung recedes from the chest in proportion to the freedom of the admission of air. In expiration, with the contraction of the chest, the lung appears to come closer to the opening in the chest wall, while it really contracts closer to the hilum. With large free openings sufficient to admit the hand, the lung in two or three expirations collapses to its hilum and remains there stationary without the slightest effort at expansion if the balance of pressure within the pleural cavity and trachea is equal or when the greater resistance is offered in the upper air passages. An erroneous conclusion has been drawn by some experimenters, and the expression given in Paget's admirable work, "One may see the lung moving freely in respiration in an animal from which a great part of the wall of the chest has been removed. I have often made on dogs penetrating wounds on both sides of the chest larger than the opening of the glottis, and I know that an animal under these conditions lives a long time and dies only of a sort of gradual asphyxia." From this it would be inferred that the lung had an expansive power of itself, but this is not the case; the dog under such conditions lives for a time because in each rapid, jerky inspiration there is a vacuum or diminution of atmospheric pressure in the pleural cavity and a moderate filling of both lungs; but make these openings large and free and there will be an immediate collapse of the lungs in the respiratory act. With one pleural cavity open, divide the mediastinal sep-

tum so that the air passes freely into both cavities and there is an immediate and permanent collapse of both lungs without the slightest effort at re-expansion, either in inspiration or expiration. If one pleura remains intact and the other has free access of air the lung in the open pleura collapses on inspiration but expands on expiration, particularly when resistance is offered to egress of air in the upper air passages; by this method the air in the lung on the uninjured side in expiration is forced into the collapsed lung in the open side. I have shown by complete occlusion of the trachea with one pleura open and the other closed that an alternate expansion and contraction could be produced by the exchange of air from one lung to the other, the collapsed lung expanding in expiration and contracting in inspiration, the other lung performing the reverse of this action.

The first opportunity to observe this action of the lung in the human subject was afforded me in the case of a policeman injured by the explosion of a bomb in the Haymarket riot May 4, 1886. A considerable portion of the lower part of the right chest was carried away; the opening was so large that the hand could be inserted into the pleural cavity. The lung could be observed contracting slightly in every inspiration; with the mouth open and the upper air passages free it expanded but very little in expiration; if, however, the upper air passages were closed when the patient expired the lung filled the entire chest cavity, and when an effort at coughing was made a hernia of the lung resulted. The patient succumbed in thirty-eight hours from the effect of continued hemorrhage from extensive laceration of the liver.

A second case, a bullet wound in the seventh intercostal space on the left side in the post-axillary line. The man stated that his antagonist shot from the left and behind. The question arose, was the diaphragm penetrated, and if so, was the stomach injured? The house surgeon, under my direction, enlarged the opening, resected the ribs to examine the diaphragm and stomach through the chest, which was the easiest route. It was found when the chest was opened that the bullet had penetrated the diaphragm about two inches from the chest wall; this opening in the diaphragm was enlarged and the finger inserted into the peritoneal cavity; the stomach was found uninjured and the opening in the diaphragm was closed. The wound in the lung could be readily examined; when coughing was produced the lung protruded from the chest wall, when he inspired it again contracted, it could be easily retained in the wound. The admission of air to the pleura produced no unpleasant symptoms, it only increased the frequency of respiration.

A third case, Miss M., admitted to Mercy Hospital June 11, 1896, for the drainage of a small cavity situated in the upper portion of the lower lobe of the right lung, under the fifth rib and between the scapula and spine. In resecting and elevating the rib the pleura was torn, the lung immediately collapsed and could be seen expanding on expiration and contracting on inspiration. The pleura in the neighborhood of the opening was irritated and the flap replaced; the intention was to perform a second operation after adhesion of the lung had taken place. The anesthetic was suspended when the chest was opened, there was no marked dyspnea and the respiration was only slightly increased after the patient was returned to bed. She felt no inconvenience nor discomfort from the resulting pneumothorax. The quantity of expect-

toration rapidly diminished and when she left the hospital it was only about one third of what it had been previously. Two months later it was still more reduced and she refused to return to the hospital for the completion of the operation. May 20, 1898, I succeeded in locating this patient and made an examination. I found the cavity had increased in size and the quantity of expectoration was about double what it had been when she was first admitted to the hospital. She still refused operation.

It is not believed that the absorption of the air by the pleura produces any deleterious effects; as a rule it takes place slowly; cases have been reported in which the air disappeared from the chest very rapidly. Fowler and Godlee state that a quantity of air sufficient to give a tympanitic note all over one-half of the chest completely disappeared in three days. If the air remains long in the chest the oxygen is absorbed and the carbon dioxid and nitrogen remain. In my experiments, injecting the chest with nitrogen, it was found by means of the radiograph that at the end of five weeks there was scarcely an appreciable diminution of the quantity of gas in the pleural cavity. This demonstrates that pure nitrogen gas is very slowly absorbed. The length of time required for the absorption of a given quantity of sterilized air by the pleura can be easily determined by repeated X-ray exposures. The above mentioned experiments as well as the clinical effusions into the pleural cavity demonstrate that the dyspnea and other unpleasant symptoms of pneumothorax are not due to the diminished respiratory exchange from compression, nor due to the effect on the pneumogastric by the contraction of the lung.

There are no definite data to show that the sudden contraction of the lung upon the terminal filaments of the pneumogastric has any effect in producing the unpleasant symptoms that occasionally occur in pneumothorax. I do not see any good grounds for believing that the displacement of the mediastinal organs produces a kinking of the large arterial or venous trunks at the diaphragm and in that way hampers the heart's action. We have the same degree of displacement of the mediastinum with effusion and hemorrhage without these unpleasant effects. We can allow, experimentally, the mediastinal contents in dogs to pass far to the left, and if they are immobilized there the dog's respirations are but little interfered with. This condition would apparently place the vessels at their greatest disadvantage as far as the outlets in the diaphragm are concerned, still produce no marked effect. It has been suggested that the increased blood pressure by the large quantity of blood forced into the general circulation by the contraction of the lung produces the unpleasant symptoms of pneumothorax. This theory is very far-fetched and I recall no analogous train of symptoms produced from increase in blood pressure by its being forced into the general circulation from other parts of the body. The most pronounced and dangerous manifestation observed in my experiments was when a medium sized opening, two inches in length, was made in an intercostal space and the air allowed to pass in and out with some opposition. The lung on the open side gradually contracted to the hilum; the mediastinal septum and contents flapped to and fro in respiration like a sail during a lull; when the dog inhaled, the mediastinal septum concaved greatly to the uninjured side; when he exhaled, it convexed to the opposite side. The chest

ceased to be a cylinder for the piston, the diaphragm, in the respiratory act. The mediastinal septum became a second diaphragm which contracted and destroyed the aspirating or piston power of the true diaphragm. With this motion of the septum there was comparatively no exchange of air in the lung, there was merely a variation in the shape of the lung; the septum soon became emphysematous and ruptured. The dogs in this experiment had rapid, panting respiration, which shortly ceased. The respiration could be easily restored by placing the hand over the opening in the chest wall with the diaphragm either concave or convex; by keeping the hand in position for a few minutes, the cyanosis would disappear and the animal reacted to his normal condition, proving that it was not the displacement of the mediastinal organs to right or left, not the diminution in the respiratory area, but the absence of secure pressure which forced the air out of the lung on the healthy side in expiration and aspirated it in inspiration. The mechanism of this action can be readily demonstrated on a half-filled rubber bag. I am convinced that the dyspnea following opening of the pleural cavity is due to the vibration of the mediastinal septum and contents destroying the piston action of the diaphragm.

In support of this theory I wish to call attention to the methods of relief reported by different operators in cases of dyspnea following opening of the pleura in surgical operations on the lung or pleura. The operators closed the opening regardless of the condition of the lung, as far as contraction and expansion were concerned, still the patients were relieved. Delagénière filled a pleural cavity with water to prevent dyspnea after he had resected the rib and removed a very large quantity of pus from the cavity. It can be seen from this case that the respiratory area was not increased, the quantity of blood in or out of the lung was not changed and the pneumogastric filaments were not interfered with, but the chest cylinder was rendered complete by the immobilization of the mediastinal septum. Covering the opening in the chest with gutta percha to prevent the intake and egress of air would have accomplished the same result. When a drainage tube has been inserted into the pleura and dyspnea occurs the occlusion of the tube relieves it.

I found that by placing a forceps on the collapsed lung and drawing it into the opening the dyspnea was immediately relieved and respiratory movements were at once resumed, a forceps placed on the hilum of the lung immobilizing the septum had the same effect. I also noted that if the lobe were secured in the aperture and only partially filled it, it did not take part in the respiration, but the dog was relieved, due I believe to the steadying of the mediastinal septum. The plugging of the trap door orifice with the lobe or suturing it to the margin was the best method for relief of the dyspnea. Carl Bayer (*Prag. Cent. für Chirur.*, Leipsig, 1897, s. 37), when operating in a case drew up the collapsed lung and sutured it to the margin of the wound. The symptoms of dyspnea and collapse disappeared and this portion of the lung filled and emptied in respiration.

Infection of pleura.—There is great danger of infection when the pleural cavity is opened; this is particularly true in experimental work. The greatest fatality in operations on the lung in dogs and monkeys has been from a suppurative pleuritis, not alone on the side which was operated but on the opposite side; this was emphasized in the detailed reports of the

experimenters, Gluch, Bloch, Schmid and Biondi. Just why a pleurisy should so frequently occur on the opposite side is not known, unless that in the dog the infection is transmitted through the thin mediastinal septum. The same pathologic condition has been noted by surgeons in the removal of tumors of the chest wall in which the lung was involved. The pleura of the dog is much more susceptible to infection than the peritoneum, or better, it has less power to resist infection than the peritoneum. The pleuritis may be of the dry fibrinous variety, or it may be associated with a large serous effusion. (Note experiment on April 24, in which the effusion was so great as to fill the pleural cavity on the side operated and to compress the lung on the opposite side.)

Septic pleurisy of a virulent and fatal character takes place with pneumothorax when there is a rupture into the pleura of a septic accumulation which previously communicated with the external air, as a bronchiectatic cavity, gangrene, suppurating or tubercular foci, subphrenic abscess, etc. West, Walsh and Fraentzel claim that 90 per cent. of all cases of idiopathic pneumothorax are due to tubercular phthisis. Havershon, in 1357 postmortem examinations of phthisical subjects at the Brompton Hospital, from 1885 to 1896, found that septic pneumothorax had occurred in 87. Paget reports a case of septic embolus of the lung and pneumothorax occurring in typhoid fever. Rupture of the lung has taken place through the alveoli without any recognized pathologic condition. T. E. Adams³⁶ reports a case of pneumothorax with rupture of lung from an occlusion of the glottis. The dyspnea was sudden in making its appearance; there were marked physical signs of pneumothorax; its disappearance was rapid; the air was entirely removed in three weeks; there were no symptoms of inflammatory trouble in the lung; the author attributes this fact to the arterial and venous ischemia induced by compression. J. Ashhurst, Jr., reports a similar case following contusion of the chest with glottis closed; no fracture of ribs; it was followed by emphysema and hydrothorax; patient recovered without operation. Pneumothorax has been present in numerous cases of subphrenic abscess rupturing into the pleural cavity.³⁷ Pneumothorax associated with these infective processes has a great mortality; few, however, of the cases die immediately; most of them succumb to the secondary effects of the pleuritic infection.

Diagnosis of pneumothorax.—The diagnosis of pneumothorax, either traumatic or idiopathic, is not difficult. The latter (idiopathic pneumothorax) is due principally to tuberculosis; 3 to 8 per cent. of tubercular cases have pneumothorax (Eichorst, Guttman, His). The absence of respiratory sounds, the distant bronchial breathing, the tympanitic percussion note, the displacement of the mediastinal contents and diaphragm, the bulging of the intercostal spaces and, if needed, the more positive evidence of the radiograph, confirm the diagnosis.

Treatment.—The treatment of pneumothorax depends upon the indications in the individual case. The traumatic cases rarely require surgical interference. Where, however, the displacement of the mediastinal organs is great and the dyspnea is distressing, it is an indication that there is a valvular opening which, with the jerky inspirations and fre-

quent coughing, has produced a plus pressure in the pleural cavity on the injured side. This is often associated with an accumulation of blood and serum and may readily be relieved by a paracentesis or by the introduction of a small trocar protected with cotton after the manner of a culture tube protection. The question would naturally arise, should paracentesis be performed in every case? It should if the relief of the air and fluid in the cavity were the only considerations, but as there is a laceration of the lung which must be closed, that organ is held compressed and immobilized by the air while repair of the lesion takes place. If the lung were allowed free expansion it would require a much longer time to heal the laceration and if the air were aspirated from the chest it would refill through the original rupture. If the trocar is not convenient and the symptoms are alarming, the scalpel may be used to make an opening close to the upper margin of the ninth rib directly below the angle of the scapula; Fraentzel and Senator favor this incision. Netter has shown that tubercular bacilli are always present when the pneumothorax is due to the rupture of tubercular foci in the lung, and that pyogenic and saprogenic germs are frequently found. The majority of cases of penetrating wounds of the chest pass through an aseptic course to recovery. When, however, the symptoms of septic pneumothorax with effusion are present, there is positive indication for immediate and free incision. The scalpel of the surgeon is too often withheld in this class of cases until the patients have passed beyond the possibility of recovery with its aid. An incision here can do no harm, can be performed with a local anesthetic and will save many lives if resorted to early. This rule with additional emphasis should govern the treatment of idiopathic pneumothorax, as it is practically always associated with septic pleuritis of a virulent type; if curable at all it is by early drainage, in occasional cases, in the early stage, irrigation with physiologic salt solution; later, possibly with a slight stimulating antiseptic. I believe irrigation of pleural cavities greatly overdone; the same may be said of irrigation of wounds in general. Free drainage is all that is necessary after the surface is once granulating, which practically protects it from infection and absorption by the exosmosis of the fluids. Perforations of the lung close rapidly, therefore the drain should be removed as early as possible. The treatment of pneumothorax resulting from operations on the chest wall will be considered under pneumotomy and pneumectomy.

Hernia of the lung is a very rare occurrence; there are occasional cases mentioned through the literature, the histories of which are very interesting. Herniae may be divided into two classes, simple and compound. The former, simple, includes those with internal laceration of the chest wall without an opening through the skin, and are produced by blunt objects which fracture the ribs or perforate the internal thoracic wall in the intercostal spaces. The compound are those associated with penetrating wounds of the thorax; here the lung is exposed in the wound or protrudes through the chest wall. The mechanism which produces the protrusion may be readily understood. The contractions of the chest wall on the same and opposite sides compress the air in the lungs; the opposition afforded the egress of air in the upper air passages produces intra-pulmonary tension which is relieved by the escape of the lung through the fissure. It is

³⁶ London Lancet, 1887, Vol. I, p. 799.

³⁷ Inter. Clin., Philadelphia, 1894, Vol. III, pp. 159-161.

surprising what little pressure placed on a rubber tube inserted in the trachea is necessary to cause the lung to protrude many inches through an opening in the chest wall. A pressure equal to four inches of water suffices. A hernia may or may not have a true hernial sac of pleura, depending upon its etiology and the rapidity of its formation. In hernia of the lung we do not include the protrusions of the lung above the first rib into the triangular spaces of the neck when they are not associated with injury, nor that produced at this point by artificial respiration, as the case of Chosu of Brussels. The symptoms and the physical signs with the location of the protrusion are so characteristic that they can scarcely admit of error in diagnosis. An exception to this is when a hernia is associated with emphysema.

Treatment.—The question of treatment of the first class of cases, simple hernia, can be disposed of by fulfilling the indications of reduction and retention. The latter may be accomplished by a compress, which should be inelastic and fit the opening snugly. If the case has become chronic, operative treatment for closure of the opening in the chest wall may be instituted (Tuffier's and Reclus' cases). Compound hernia of the lung forms one of its most interesting though not practical pathologic conditions, as the accident is so extremely rare. I consider the cases reported of great value as an index of the extent to which the lung may be interfered with in a surgical way. I take the privilege of quoting verbatim from Paget the case of Rolandus, published in the year 1499: "Called to a citizen of Bologna on the sixth day after his wound, I found a portion of his lung issued between two ribs; the afflux of spirits and humors had determined such a swelling to the part that it was not possible to reduce it. The compression exercised by the ribs retained its nutriment from it, and it was so mortified that worms had been developed in it. They had brought together the most skilful surgeons of Bologna who, judging the death of the patient to be inevitable, had abandoned him. But I, yielding to his prayers and to those of his parents and friends, and having obtained the leave of the Bishop, the master and the man himself. I yielded to the solicitations of about thirty of my pupils, and made an incision through the skin, the breadth of my little finger-nail away from the wound, all round it. Then, with a cutting instrument, I removed all the portion of the lung level with my incision. The wound resulting from this resection was closed by the blood issuing from my incision, and was dressed frequently with the red powder and other adjuvants. By the grace of God it cicatrized and recovery took place. It is true that one had to wait long for it. The patient, with his master, Rolandini, has since then made the voyage to Jerusalem, and has returned in good health. If you ask me what I should have done in this case if I had been called to it at once, I answer that I should have dilated the wound with a small piece of wood, keeping the lung warm with a cock or a fowl split down the back, and should then have reduced it, and kept the wound open till the portion of the lung was wholly mortified. If you still question me, to know how this man can live without his lung, I answer that the part remaining within the chest profits by the nutriment destined for the whole of the lung, and so is developed, and that nature has been able to create supplementary parts in it, which is an easy thing in an organ which is soft and near the warmth of the heart."

A similar case was reported by Tulpin in 1674, in which the protruding portion was ligated and cut off with the scissors. Couvey collected fourteen cases treated by removal of the protruding lung, with twelve recoveries. A. Demons reports a successful case. The method of treating the stump in these cases consisted of ligation, with retention of stump in the wound, amputation with the cautery, or dressing with antiseptics and allowing the lung to slough or desiccate, as the tendency might be in the individual case, depending upon the circulation.³⁸ The fact that this class of cases recovered, after pneumectomy with the retention of the stump in the wound, led me to the experiment of amputation of the lung with extra-pleural treatment of the pedicle and the production of primary hernia of the lobe, to be removed with secondary amputation. In compound hernia it is not necessary that the protruded portion should be amputated; if seen early it is better to cleanse and return the lung and resort to drainage of the most dependent portion of the cavity, close the opening in the chest by suture of the separate layers, and if necessary by a catgut suture of the fractured ribs.³⁹

Wounds of the lung.—This subject is so extensive, and the cases are so common, that a volume might be devoted to their enumeration and analysis; still, they may be so grouped into classes for their general consideration that it will only be necessary to cite cases typical of each class. We will include here the cases of secondary infections following fracture of the ribs, stab, bullet and pointed object penetrations. Infections following simple fractures of the ribs are very rare, considering the frequency of this injury. They are readily diagnosed and the treatment should be the same as that for compound infected injuries, considered later. A case illustrating the secondary infection following fracture of the ribs is reported by Maydl,⁴⁰ in which a large quantity of the purulent fluid was removed from the lung three weeks after the accident, the pleura having been drained of blood and serum immediately after the injury; case recovered.

Stab wounds of the chest are common, but are rarely associated with serious symptoms. I recall a case which occurred in the Cook County Hospital; a patient received fourteen stab wounds in the posterior wall of the chest with a knife-blade 2½ inches in length; many of these perforated the chest wall, still the patient suffered no serious inconvenience; there was a slight pneumothorax and hemoptysis for the first two days; the temperature did not exceed 100 degrees at any time and he made an uneventful recovery. This is illustrative of the ordinary course of stab wounds of chest with pocket knives. The lung, like the intestine, is not injured by a stab wound unless it be adherent or the penetration takes place at its hilum or mesentery. Hemorrhage, pneumothorax and hemoptysis are not common after stab wounds. The indications in these cases are to clean and seal the external wounds; administer the necessary medicines to prevent coughing; never probe or explore; refrain from protracted examinations, and allow the patients to remain in the recumbent position. If infection follows they should be treated the same as infected bullet or other penetrating wounds.

Bullet wounds of the chest produce a great variety of pathologic conditions, and still a very large percent-

⁴⁰ Wien. Klin. Rund., June 23, 1895.

age of the cases pass through an uncomplicated course to recovery. This great difference in the course and results of cases is due to the portion of the lung penetrated, the size and character of the missile, the involvement of the large vessels and bronchi, the presence or absence of infective material and the sequence of infection. Penetrations of the periphery of the lung by bullets, as a rule, do not produce serious symptoms; there is but slight hemoptysis; this is estimated to be present in less than 20 per cent. of the cases of bullet perforations of the lung; its presence does not positively indicate perforation, though practically it has that significance; there is no appreciable hemothorax; shock, pallor, feeble pulse, apparent anemia in bullet wounds of the lung do not necessarily mean hemorrhage, as they are often pronounced when there is no appreciable quantity of blood in the pleural cavity. This fact must never be lost sight of when thoracotomy is contemplated for the relief of hemorrhage. There is usually diminution of the respiratory action on the injured side and occasionally a limited pneumothorax; on the third or fourth day after the injury there may be evidence of a circumscribed traumatic pneumonia which rapidly subsides and then the patient is convalescent. Contrast this with the course of a case in which the bullet penetrates the hilum and is associated with severe intra-thoracic hemorrhage. The patient, after the injury, is collapsed, becomes pulseless, his respirations are increased in frequency and are of a sighing character; the lung on the injured side has collapsed and within a short time the patient succumbs. This is the class of cases in which surgical interference can not be considered for the relief of hemorrhage, as they terminate fatally before surgical interference is possible. It is in cases of hemothorax where the escape of blood is slow or secondary that thoracotomy with ligation, compression or cauterization of the bleeding point comes into consideration. It has been suggested that allowing the lung to collapse would produce hemostasis. Clinical experience and experiments have demonstrated that it has no such effect, that induced pneumothorax does not act as a hemostatic and therefore should not be resorted to. In reviewing the cases of hemothorax that have been treated by open incision and ligation I have been impressed by the almost unanimous failure of mention of unpleasant symptoms from the pneumothorax produced by the operation. Whether the absence of symptoms was due to the fact that the lung was collapsed before the operation by the accumulated air or blood I do not know, but the practical fact is the same, and its clinical significance is that under these conditions the chest may be opened with little apprehension as to the pneumothorax producing unpleasant symptoms. This observation might indicate the filling of the chest with fluid or air before performing pneumotomy or pneumectomy. Of 98 cases of fatal gunshot wounds of the chest occurring at the siege of Strassburg 24 were due to hemorrhage into the pleural cavity alone. (Beck.) Of 65 penetrating wounds of the chest in military practice by Sir Wm. McCormack and Fisher 36 terminated fatally, which is a very much greater percentage than appears in civil practice. External hemorrhage is not common with gunshot wounds of the chest; occasionally there may be some bleeding from vessels situated in the outer portion of the thoracic wall. It must not be forgotten however, that in wounds of the intercostal and mammary arteries the

hemorrhage is more likely to be internal than external and these small vessels should be examined first in all operative procedures. We have no means of determining without exploration whether the hemorrhage is from the chest wall or the lung itself. Quénu, Michaux, Berger, Delorme and Reclus warmly advocate surgical interference when the evidence of hemorrhage is unmistakable. Omboni⁴¹ excised two different portions of the same lung for a bullet wound; the anterior margin of the upper lobe had a V-shaped piece removed, followed by accurate catgut suture; through the same opening of the chest a portion of the lower lobe was drawn forward, ligated *en masse* and excised; drain inserted. Patient died on sixth day. Postmortem: Fatal pyemia from sub-serratus magnus infection; stump in good condition and healing; cause of death, defective drainage of external portion of wound. V. Richards⁴² successfully excised pneumocele following penetrating wound of the thorax. Delorme and Robert operated, but patients were in such bad condition that they died within fifteen minutes after operation.

From careful examination on the cadaver and from my experiments on the dog, I am convinced that many lives can be saved by early intervention in cases of intrathoracic hemorrhage either by ligation with or without amputation, suture with catgut or cauterization with the Paquélin. I have little confidence in our ability to produce hemostasis by packing such an elastic and easily infiltrated tissue as the lung; the suture is preferable and should be performed with a round needle and absorbable material; the greatest antiseptic precaution should be exercised.

The secondary changes which occur after bullet wounds, as pneumonia, abscess, gangrene, pyohemothorax, empyema, septicemia (sapremia) and pyemia are of much greater importance and deserve more attention than is usually given them either in the text-books or in recent monographs on this subject. The pneumonia in many cases is limited, in others it may involve a lobe or an entire lung; it often has marked evidences of acute pyogenic infection extending even to gangrene of the infected portion. Pyohemothorax and empyema may occur shortly after a bullet wound of the chest. The patient shows, in addition to the symptoms of depression and shock from the hemorrhage, manifestations of infection, not necessarily a great elevation of temperature but other marked evidences of septic intoxication, as dry, coated tongue, delirium, thirst, rapid respiration, etc. These symptoms usually present themselves on the third or fourth day after the injury and rapidly increase in severity until the patient succumbs from the sapremia on the seventh or eighth day unless rescued by surgical interference. The dictum of non-interference in gunshot wounds of the chest has taken such root in the profession that even unquestionable evidence of putrefaction and suppuration within the chest does not call forth active response on the part of the surgeon to afford relief. A patient with the same evidence of sapremia or septicemia in other parts of the body is immediately assisted by the surgeon, while in bullet wounds of the chest procrastination is the practice. I wish to emphasize that whenever there is evidence of putrefaction or suppuration the chest should be immediately opened and drained the same as the

peritoneum or cellular tissue would be under the same conditions. I cite here a case of this class:

J. C., male, aged 27, admitted to Alexian Brothers' Hospital June, 1895; three hours previously was shot from in front with a 44-caliber bullet which passed into the chest and fractured the fifth rib; it lodged under the skin behind near the angle of the eighth rib, which was fractured. The first day he was suffering from slight dyspnea, some pain on the right side, had expectorated a small quantity of blood and had pneumothorax. The following day his temperature was 100 degrees, pulse 94, respiration 32, tongue slightly coated. At noon of the third day his temperature was 103 degrees, dulness extended up to the axillary line in the recumbent position, tongue slightly coated, and he was mildly delirious; bronchial breathing could be heard over the upper portion of the chest behind; this was probably transmitted. Fourth day—When I arrived at the hospital at 12 o'clock temperature was 105 degrees (rectal), pulse 160, respiration 42; he was cyanotic, unconscious and in a low, muttering delirium. He was placed on the table and without anesthetic a resection of the eighth rib was made at the line of fracture. The bullet and fragment of cloth were removed from the muscle wall, also a large quantity of offensive bloody debris and fluid from the pleural cavity. The opening at the point of entrance of the bullet was enlarged and an irrigation of the cavity with sterile water was made. The day following his pulse was 132, temperature 102 degrees, respiration 36; his delirium had almost subsided and his general appearance was improved. In another twenty-four hours his temperature had dropped to 100.2 degrees, his respiration 28 and pulse 124, and his general condition was still better. From this time on his improvement was rapid. The drainage tube was removed on the sixteenth day and in three weeks he left the hospital.

This case is typical of its class, and similar cases may be observed almost any time in the hospitals of large cities. The rule is, however, that they are allowed to go on to death without surgical interference, as the following case illustrates:

M. C., age 19, admitted to Alexian Brothers' Hospital May 16, 1893. A 44-caliber bullet penetrated the anterior wall of the right half of the chest fracturing the third rib. The patient was very much shocked from the injury; pulse was 130; skin cold and clammy and countenance blanched; anxious expression; there was a marked area of dulness over the lower half of the right chest; pneumothorax of the upper half; hemoptysis was continuous but not severe. The following day the patient's temperature was 101 degrees, pulse 118, respirations 54. He requested to be discharged from the hospital and under strong pressure was persuaded to remain another day. The third day his respirations were 40, pulse 150, temperature 103 degrees. He was delirious. Operation was advised but the parents would not consent. He was taken to his home, where after surgical consultation it was decided that he could live but a few hours and that interference would be futile. The death took place five days after removal from the hospital. The attending doctor told me that his condition remained about the same until the end. The postmortem revealed a penetration of the middle lobe of the right lung and the upper portion of the lower lobe. There was a fracture of the seventh rib at its angle, the bullet had dropped back into the pleural cavity. The chest was full of an offensive sanguino-purulent fluid; there was a cloudy swelling of all the tissues, no metastatic abscesses. The cause of death was acute septicemia.

This case shows how long a patient, with this variety of infection, may live after his condition seems hopeless. I might cite many similar cases from the emergency wards of the county hospital. We hope the surgery of the future will lend a helping hand to stay the mortality from secondary infection in gunshot wounds of the chest. Simple incision and drainage may be all that will be necessary, but there should not be the slightest hesitancy in resecting one or more ribs and making a free incision in the pleural cavity in its most dependent portion regardless of the point of entrance or exit of the bullet. The clinical course and treatment of penetrations with other sharp-pointed instruments is based on the same pathologic and therapeutic principles as stab and bullet wounds;

the lung is rarely injured with these instruments and primary drainage is more frequently indicated.

(To be continued.)

REST—A NEGLECTED FACTOR IN THE TREATMENT OF GASTRO-INTESTINAL DISORDER.

Presented to the Section on Practice of Medicine at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY C. D. SPIVAK, M.D.

LECTURER ON DISEASES OF THE GASTRO-INTESTINAL TRACT, UNIVERSITY OF DENVER, MEDICAL DEPARTMENT.
DENVER, COLO.

It is not within the province of my paper to enter into the discussion of the subject of rest from a physiologic standpoint. The question of rest is only being at present approached by the physiologists of the day through the study of muscle and nerve irritability, waste and repair, sleep and the still less explored domain of "fatigue." Not until sufficient experimental data will have been accumulated will we be in a position to form a rational physiologic theory of rest. I will use the word "rest" in its most comprehensive sense—the antithesis of action. Life is action, but action is made possible by the period of rest during which the spent energies are renovated. All our organs manifest periods of action and repose alternately; some are absolutely rhythmic, as the circulation of blood; others are only intermittent, as the secretions and excretions. The organs of vegetative life are so wonderfully arranged that they take their rest without asking our permission for it. Nobody can bid the heart beat 120 times a minute, neither is one able to retain his urine at will for one week. It is different with the organs of animal life. Here automatism ceases. If he will he thinks, if he will he exercises his muscles. He knows no limit except the point of fatigue, which is the threshold of the pathologic. There is another difference between the organs of animal and vegetative life. After a continuous use of any one of the organs of animal life, be it thought, sensation or contractility of muscles, there comes a period of repose during which the organs of vegetative life go on performing their functions undisturbed. On the contrary, when the organs of vegetative life have overstepped the point of fatigue, the organs of animal life invariably suffer in consequence more or less. It is well known how digestive, circulatory and urinary troubles influence the motor, sensory and intellectual functions. Rest, therefore, can be defined as nature's *prophylactic*. It not only prevents the further breaking down of tissues, but it affords the chance for the tissues to store up new energy. In the ordinary life of a healthy individual the period of activity and prophylactic rest are balanced unnoticed and unobserved. We are unable to measure the time of activity and rest. But as soon as man deviates from the normal it then becomes evident that the two must remain in a direct ratio in order to establish the equilibrium. The greater the activity that produced certain abnormal phenomena the longer must be the rest. The length of time which is required by nature for the repair of an injury must be in proportion to the severity of the injury, and the more severe the injury the longer time is required for the perfect recovery of the disturbed functions. Rest in such cases becomes a *therapeutic* agent.

Prehistoric man, I am sure, did not know of the terms prophylaxis, metabolism, katabolism, energy, etc., and yet rest has probably been his chief, and for a long time his only, remedy. Nature has insisted upon it, "even to the extent of inflicting a twinge of pain on such as disobeyed her precepts." And notwithstanding the fact that the beneficent action of rest is so obvious, and may be said to be inherent and instinctive, so much so that even animals employ it as a therapeutic agent in surgical as well as medical cases, yet it was only in the seventies of this century that the first word was spoken in the elucidation of the question of rest. I refer to the classic lectures of John Hilton on "Rest and Pain." The surgeon was the first to recognize the value of rest. In 1878 the neurologist followed and sang the praises of nature's greatest *Materia Medica*. It was our own Weir-Mitchell who elaborated in his work, "Rest in the Treatment of Nerve Disorders," a cure that bears his name, the brilliant results of which made its author known wherever medicine is practiced. Since that time it seems as if the surgeon and neurologist have monopolized "rest." It is indeed a happy coincidence that those who suffer from pneumonia and typhoid fever are unable to walk, otherwise the physician would never think of ordering them to go to bed. In our day of multiplicity of drugs, patent and proprietary, legitimate and illegitimate, nostrum and specific, when a patient presents himself, and the diagnosis is once made, the first question is: "Which of the thousand and one drugs shall I prescribe?" Surely there ought to be one which will hit the right point. The surgeon thinks first of all of rest. The neurologist tries to secure rest. The physician alone uses the pharmacopeia first, last and all the time.

True, in looking over the scanty literature on the subject of rest one finds here and there a timid voice raised apologetically for the use of rest in cardiac, pulmonary and renal troubles. But the fear of being branded a crank makes them speak in tones not louder than a whisper, and their effort is lost in the pandemonium of the "new" and "newer remedies" craze.

I wish to raise my voice many octaves above a whisper and proclaim loudly and boldly that I employ rest, nature's greatest panacea, as my first and best weapon against the greatest foe of mankind—diseases of the gastro-intestinal tract. I know that the tendency of our time is to treat diseases of the stomach by washing, scouring, scratching, punching and electrifying the stomach. The gastro-enterologists of the country have at the present time visions bright of the oncoming time when the same *modus operandi* will be applied to that poor piece of gut which measures only twelve fingers in length—when we will be able to wash, scour, scratch, punch and electrify the duodenum. Far be it from me to scorn the work of an Einhorn, Hemmeter, Stewart or Turck. There is none who appreciates more highly the services they have rendered to gastrology than I do. I can assure you that before my stomach will perform the last functions of autodigestion I will yet wash, scour, scratch, punch and electrify a good many stomachs. But I refer more to the tendency of the time, which makes everyone who reads a book on diseases of the stomach arrive at the only conclusion that lavage is the only salvation of the stomach, and that the stomach tube will "do it all."

I take the stomach and intestine to be in no way

different from any other organ in our bodies: they are made up of the same tissues, are subject to the same insults, and their mode of repair is identical with that in any other part of the body. I do not see the difference between the symptom-complex called neurasthenia and that symptom-complex called nervous dyspepsia. Why apply the Weir-Mitchell treatment in the one and not in the other? I do not understand by what manner of reasoning one arrives at the conclusion that in the treatment of a painful limb, according to the maxim of Hilton, "the maximum of result is co-equal with minimum of disturbances," and that a painful stomach or painful intestine should not be accorded the same privileges. And lastly, it is incomprehensible to fathom the wisdom of prescribing rest for the weary limb, an exhausted organ, anywhere in the body except in the stomach. The only redeeming instance in the whole array of diseases to which the stomach is heir, and in which the rest cure is recognized as the remedy *par excellence* is ulcer of the stomach. The principle of the cure was laid down by Niemeyer, recommended by Ziemssen and especially elaborated by Leube. It is expressed by Ewald in the following words: "I know but one form of treatment which holds out prospects of success . . . and this is the rest cure . . . by which the stomach is protected from all irritating factors as a broken bone is immobilized in plaster."

Now, the surgeon does not draw a line of demarcation between an ulcerated, broken, bruised or simply inflamed limb. Rest is the *sine qua non* treatment. Go over in your mind the whole gamut of diseases of the stomach from a simple inflammation of the mucous membrane to solution of continuity, and you will find that the process, both pathologic and reparative, is the same. Why, then, not apply among other things the same remedy? I have done so and nature has rewarded me most generously.

How can rest be applied to diseases of the stomach and intestine, will be asked. It is true you can not put these organs in splints, but you can, by using one or all of the following methods, secure rest: 1. Rest in bed. 2. Diet. 3. Hot poultices.

1. *Rest in bed*.—In severe cases I follow the method of Weir-Mitchell to the letter: 1. Absolute rest in bed. Sitting is not allowed under any circumstances. The bowels are regulated; the bed pan is used. 2. Sponging the whole body every morning. 3. Isolation. 4. Massage. I have not had yet a case that required electricity. In milder cases I use my judgment as to isolation and massage.

2. *Diet*.—In many severe cases of gastro-intestinal disorders the best bill of fare is abstinence. One, two or even three days' fasting will do no harm in cases of ulcer, dyspepsias, and diarrheas of all kinds and varieties. Nutritive enemata can be employed in cases where a longer period of fasting is necessary. When food by the mouth is allowed it must be given in small quantities, no matter whether liquid or solid, and at regular intervals. Every case must be individualized as to the quality and quantity of food.

3. *Poultices*.—I shall not attempt to formulate a theory as to the action of poultices. Whether the poultices hasten the expulsion of food from the stomach as has been shown experimentally by Fleischer, or they cause the acceleration of the circulation of the blood in the abdominal viscera, is not yet definitely settled. I am certain, however, of one thing, and that is that they aid the peristaltic move-

ments of the stomach, they make the patient feel comfortable and keep him warm and at rest. *The poultices take the place of splints.* In severe cases the poultices are applied constantly during the day for one and two weeks. In milder cases from four to eight hours daily.

The time allotted to me does not permit me to enter into details. Each of the three forms by which rest of the gastro-intestinal tract may be secured would require a separate essay. I will therefore limit myself to the recital of the histories and results of a few cases which have undergone the rest cure.

Case 1.—Referred to me by Dr. J. T. Eskridge. J. H. S., Plattville, Colo., aged 31 years, male, merchant. Family history negative. Had continued fever in 1887, lasting for two weeks. In 1890 had influenza. These two attacks left him in a weakened condition. For the last years the following train of symptoms have developed gradually: Headache almost constant, at times accompanied with pain in back; distress and heaviness after meals; burning sensation in stomach from one to two hours after ingestion of food, which is sometimes relieved by taking baking soda, oftener not. Appetite is good, bowels regular; has not lost perceptibly in body weight; suffers occasionally from jerking and twitching of muscles, has attacks of despondency and melancholy and spells of crying; once in three to four days, sometimes at longer intervals, becomes dizzy when commencing his meals; sleeps well; suffers from nocturnal emissions quite frequently; attacks of frequent urination. Physical examination of mouth, chest and abdomen negative, except a slightly coated tongue, and some tenderness over pit of stomach and transverse colon. Repeated examinations of stomach contents after various meals, at various times revealed a total acidity varying from 90 to 140. Not being able at that time to absent himself from home and to take the rest cure, he was ordered to subsist on nitrogenous diet; he was given strychnin in small doses, sod. bicarb. after each meal, lavage every other day. His symptoms were greatly mitigated. The headaches diminished both in frequency and severity; he could concentrate his mind; his weight increased. Yet he was not cured from the burning sensation in his stomach. He had to take soda every day, and at times even large quantities would not relieve.

Six months after he first consulted me he decided to try the rest cure. In addition to absolute rest in bed he had hot poultices applied to his abdomen twice a day, cold sponging every morning and his diet regulated. He was not given any soda, neither was his stomach washed. The burning sensation gradually diminished and at the end of fourteen days he was entirely free from this annoying symptom. Contrary to my advice that he remain in bed at least two weeks longer, in order to insure a permanent cure, he returned to his home. He informs me (now one year after the treatment) that he is doing well, and that only within the last two months he has once in a while the recurrence of slight attacks of heartburn.

Case 2.—J. O., female, 24 years of age. Married four years. Has no children. Parents healthy. Was well until five years ago, when she had an attack of influenza which left her with a bad cough, and she gradually grew worse. She came from Portland, Ore., to Denver two years ago. She markedly improved. For the last three months she commenced to cough and the expectorations were at times blood-streaked. Bloating and pressure after meals very annoying. At first she vomited after meals once or twice a week; later it became more frequent. Can not keep anything on her stomach for the last five days. She has retained, however, her appetite for food. She suffers from night sweats and violent attacks of coughing. Physical examination revealed dullness over the apex of and scattered areas of moist râles heard over the left lung, anteriorly and posteriorly. The stomach contents showed a great quantity of mucus and diminished acidity. She was sent to St. Joseph's Hospital; absolute rest enjoined and carried out. No food was given for the first twenty-four hours. For the next two days she was allowed small quantities of somatose. Hot poultices applied to abdomen constantly for first four days, then six hours daily. Cod liver oil inunctions daily. No medicines were given by the mouth, except a hypodermic injection of strychnin once a day. At the end of four weeks she ate meat at each meal and drank two quarts of milk without experiencing any distress after; has gained six pounds in weight, no night sweats, no harassing cough. She became pregnant five months after she was discharged, miscarried on the third month, and at the time of this writing, fourteen months after the treatment, continues in good health.

Case 3.—Referred by Dr. S. A. Fisk. J. H. P.; 25 years old; student. Father's mother, and sister of patient died of lung trouble. Has had lung trouble for two years. Dr. Fisk informed me that he has "considerable infiltration on the right side of his chest, and some beginning on his left; a mitral systolic lesion with a slightly enlarged heart." For four months suffers from diarrhea; has from four to five watery stools daily. No pain in abdomen; appetite fair. Pulse 110, temperature elevated in the afternoon.

Treatment.—Absolute rest in bed. No food for twenty-four hours. Somatose for two days, and after that scraped meat and kephir. For the first five days gave orphol in five grain doses, and washed the bowels twice. After that gave strychnin, one-thirtieth of a grain three times daily. He was in bed three weeks. The diarrhea never returned. Four months after he was discharged Dr. Anderson of Colorado Springs, referred him to me for the examination of his feces, which contained some peculiar extraneous matters. As his feces did not contain at that time anything peculiar, I have examined a specimen under the microscope and found numerous ova of *tænia solium*. By appropriate treatment have removed without any trouble a tape worm. The patient is now (twenty months after treatment) in Switzerland and has not had an attack of diarrhea since.

Case 4.—Referred by Dr. Clayton Parkhill. F. F.; 44 years old; female. Father subject to rheumatism; mother died of a paralytic stroke. On Dec. 7, 1896, noticed a growth in the left breast, which was diagnosed by Dr. Parkhill as cancer, and which he removed. Six weeks after the operation commenced to feel pain in the epigastric region, aggravated by taking food, which continued for the last five months. Belches a great deal. Appetite fair; bowels costive. No nausea, no vomiting, no heartburn. Test meal found well digested. HCl present.

Treatment.—Rest in bed, poultices to abdomen. Meat diet and kephir. Nux vomica fifteen drops three times daily. The pains gradually subsided, and after three weeks she left the hospital cured.

Case 5.—Referred by Drs. Eskridge and Wetherill. E. S.; 42 years old; female; single. Family history negative. At 9 years of age she had scarlet fever, since which time all her troubles date. She had attacks of dysentery periodically. Intense headache, front and nape. Frequent attacks of diarrhea preceded by pain in intestines, usually over colon. Great irritability in rectum and bladder. In 1891 had a cystic tumor removed from her right breast. In June 1894 had her uterus scraped, which relieved in a measure the irritability in the bladder and rectum. Four months after the operation a tape worm was removed. In February 1895 hysterectomy was performed and the right ovary removed. The annoying symptoms were not abated in the least. In June 1895 right nephorrhaphy was performed. In September 1896 she came under my observation, Dr. Wetherill having, after careful examination, refused to operate on her rectum, which he found in a normal condition. After watching her symptoms for some time I have come to the conclusion that she suffers from membranous enteritis, and probably has suffered from the same malady all her life. Her treatment consisted of absolute rest in bed, hot poultices to abdomen, and high irrigation in colon with a solution of resorcin. Her diet consisted of meat, kephir, bread and plenty of butter. She showed marked improvement from the start, and life was no longer a curse to her. I can not claim that she is entirely cured. The pains in her abdomen recur once in a great while, and she then sheds a good amount of membrane, but the intervals of freedom from pain and annoyance are long, sometimes lasting four and five weeks, and the attacks are never as intense. She has taken three courses of rest cure, each continuing five, four and three weeks respectively.

Case 6.—Referred to me by Dr. D. H. Coover. D. H. C.; 38 years old; married. Father and mother of gouty disposition. Enjoyed fair health when a girl. Having resided in a malarial region, she suffered from intermittent fever. For the last fifteen years suffered intensely from pain in abdomen and diarrhea. She was never free from pain more than a few days at a time; suffered from neuralgic pain in head and sciatic nerve. As far back as 1885 she noticed in her evacuation shreds of mucous membrane, sometimes a full cast of the bowel. During the last few months the pains became unbearable; she could not sleep, was despondent and very miserable. She came under my notice June 1897.

Treatment.—Rest cure absolute, hot poultices. No food for the first twenty-four hours, and small quantities of somatose during the next four days. High irrigation of the bowel, with resorcin solution at first every day for five days, then once a week; five grain doses of orphol. At the end of the first week

she was rewarded for her enforced rest by having a spontaneous, well-formed stool, an event which has not occurred for many years. She remained in bed for three weeks. Four weeks after she had a slight relapse and was again ordered to remain in bed, and this time she remained for about four weeks. At the time of this writing, one year after the rest cure, she is in good health; has not had a single attack of diarrhea or abdominal pain.

Case 7.—Referred by Dr. S. A. Fisk. R. S.; 39 years old; female; Mexican. Three years ago had a bilious attack—headache, diarrhea and vomiting, lasting for one day. Since that time suffers from diarrhea. Has one well formed stool every morning, and four to five evacuations during the day, the last stool usually containing some mucous and shreds of membrane. She has never had a movement during the night. Stools are watery and very offensive. She has no pain in abdomen, no pressure or distress. Has lost twenty pounds in weight since her first attack. Took a course of treatment in Carlsbad and Paris, with only slight and temporary relief. She came under my treatment in September 1897. I have pursued the same course of treatment as in No. 6. Being of a highly nervous temperament, as soon as the diarrhea stopped she left for Tucson, Arizona, where she kept up the rest cure for some time. Dr. Rodgers of Tucson, under whose care she was, writes to me that she has no diarrhea and that her stools are perfectly normal.

Case 8.—Miss M. G.; 27 years old; medical student. Parents healthy. She enjoyed good health until within six months, when she commenced to feel pain in her stomach after meals. Pain is localized, aggravated by pressure and by taking food, and even water. The pain grew gradually worse, and her physician had recourse to opiates. No nausea, no vomiting, no heartburn, no belching, no headache. Appetite good; bowels regular. HCl 80. She remained in bed only ten days, as she was anxious to come up for examination in May (1898). Hot poultices were applied six hours daily. Somatose given during the first three days, and later small quantities of milk and lime water every half hour. At the end of the ten days she was free from pain. At the time of this writing, four weeks after the rest cure, she complains of slight pain once in two or three days.

Case 9.—Referred by Dr. Mullin of Aspen, Colo. M. B.; 52 years old; female; German. Family history negative. Fourteen years ago had an attack of typhoid fever. Seven years ago, immediately after drinking a cold glass of beer, was taken sick. At first she felt as if there was a load in her stomach, which continued for several days. She suffered on and off from abdominal pain, since. In 1893 had severe pains, and her physician washed her stomach and put her on a milk diet, which relieved her very much. Whenever she would have an attack this mode of treatment was employed with success. In January 1898 had influenza, and since that time the condition of stomach became worse. Pain is aggravated by taking food, by exercise, and is worse toward evening. The pains are especially severe from 8 to 11 P.M. No headache. Appetite fair. Bowels have been always regular; constipated since the attack of influenza. She came under my treatment May 14, 1898. The stomach contents revealed nothing abnormal. On palpation a tumor was found in the right abdominal cavity, movable on respiration, and making excursions from under the ribs down almost to the brim of the pelvis. The diagnosis of a movable right kidney was substantiated by Dr. C. A. Powers.

Treatment.—Absolute rest in bed, hot poultices, massage, cascara sagrada (Stearn's) for the constipation, and strychnin. The pain gradually diminished. After the first week she has not had a single severe attack. Sleeps well. Her appetite is excellent, and if she remains in bed for three weeks longer, I expect, that with an abdominal bandage so fitted as to keep the kidney *in situ*, she will remain comfortable through her life.

ANALYSIS OF THE CASES.

I have chosen from my records of over one hundred cases treated by rest-cure during the last two years these nine cases with a view of illustrating the groups of diseases wherein I found my method to give satisfaction.

Case 1 represents a type of hyperacidity upon a nervous basis. Washing of the stomach and alkalis were of no avail. Being a case of neurasthenia with hyperacidity only as a predominating symptom, rest logically suggested itself to my mind.

Cases 2 and 3 represent the usual type of tubercular patients, the first suffering from vomiting, the other from diarrhea, both conditions being analogous, and only differing from one another as to the seat of the irritability in the digestive tract. To let such patients eat, drink and walk about is simply to add insult to injury. All around rest for body, stomach and intestine is clearly indicated.

Cases 4 and 9 represent types in which the suspicion of cancer is very strong. Case 4 had a cancer removed from her breast and case 9 had all the symptoms diagnostic of cancer, her age, the constant pain, the emaciation. The first case proved to be a severe dyspepsia, the other a floating kidney.

Cases 5, 6, and 7 represent various types of enteritis. It is my belief that through a mistaken diagnosis case 5 was unsexed and otherwise mutilated.

Case 6 convinced me that all cases of enteritis without an organic lesion are amenable to treatment, and case 7 presents a point of interest that membranous enteritis does not necessarily follow the letter of the text-books, and may be present without severe pain.

Case 8 represents a type of cases in which the diagnosis of ulcer or erosion of the stomach is very probable but not certain. The age of the patient, the localized pain increased by pressure and by the taking of food, and the slight hyperacidity all point to ulceration or erosion. The diagnosis may be doubtful, but the beneficent result of the rest treatment is certain.

CONCLUSIONS.

1. It is indicated in all dyspepsias, the underlying cause of which is a deranged nervous system.
2. It is indicated in all cases where abdominal pain is present.
3. In all cases of acute and chronic diarrhea.
4. In hemorrhage from the stomach or intestines.
5. In all cases of moveable or floating kidney.
6. In all tubercular cases suffering from disturbed digestion, be it stomach or intestine, and especially those that have a vacillating temperature record, and as there are but few cases of tuberculosis that do not suffer from some form of gastro-intestinal disorders, the rest cure is indicated in 50 per cent. of all cases of tuberculosis. Not only are they relieved from their annoying digestive symptoms, but their general condition markedly improves.
7. I have yet to learn of a disease of the gastro-intestinal tract where the rest treatment is contradicted.

I will close my paper by a quotation from Hilton's "Rest and Pain," which I have altered somewhat to meet the occasion. "In all diseases of no matter what nature, of the gastro-intestinal tract, when the evidence of disease is in organic lesion or in deranged function, it becomes our duty to look upon and treat the altered structures as we do contusions and laceration of soft parts and congestion of organs in any other part of the body, and to give the stomach and intestines absolute rest, to rely on nature's power to repair the injury or disturbance, and to avoid stimulants, which excite rapid circulation as much as possible. The stomach and intestines disturbed in their vital endowment become unequal to even their ordinary duties. They recover themselves slowly; they then soon become fatigued from use, and if claims are made upon them soon after injury, that is, before structure and physiologic integrity are re-required, the patient is very likely to suffer from serious dis-

¹ My prognosis came true. Patient was discharged cured, July 1.

ease of the alimentary tract. The stomach, as well as the intestines, requires absence from occupation, rest, and it should be in proportion to the severity and duration of the symptoms they present."

DISCUSSION.

Dr. H. M. McCONNELL of Pennsylvania—I do not think there is any class of cases that require rest so much as diseases of the stomach. Rest of this organ means physiologic rest. The only way to obtain this rest is to abstain from food entirely and this can only be done to a very limited extent, when it can be carried out at all. When the Doctor gave the history of his cases he did not say what they were being treated for; in some cases it is injudicious to give nitrogenous food. Some symptoms are due to auto-intoxication, and you must improve digestion in treating these cases. Take ordinary typhoid fever, a patient that takes three or four pints of milk a day is not giving the organs physiologic rest. When you take into consideration imperfect digestion, most cases of neurasthenia are cases of auto-intoxication. Physiologic rest is very important.

Dr. Tyson of Philadelphia—In speaking upon the rest treatment of gastro-intestinal troubles the Doctor has spoken of the one thing that will do more or less good in every case of these troubles; the application of therapeutic measures in these gastro-intestinal troubles is more or less haphazard. Those who look into the subject do not receive much assistance so far as therapeutic measures go. I hope the time will come when accurate methods will produce more satisfactory results. In comparison to the rest treatment of the stomach, the Weir Mitchell method is rather analogical. In my experience food is not such a necessary factor in the treatment of these conditions as many would imagine. A patient may go one, two or three days without the ingestion of food, if he is in a position not to demand any force; food is a force-producing agent largely.

Dr. H. A. WEST of Galveston, Texas—The scope of Dr. Spivak's paper is very comprehensive, because the gastro-intestinal canal undergoes serious involvement in nearly all infectious diseases, such as rheumatism, scarlet fever, measles and diseases of that class, in which the processes of digestion are seriously involved. Rest treatment is of supreme value, not only rest so far as can be accomplished by rest in bed, but by other means. And especially as regards acute rheumatism, the prognosis in this disease as regards the subse-

quent cardiac complications can be made less or even averted by such a plan of rest in bed. The whole subject is so comprehensive that one can not discuss it in the five minutes allowed him. One point would require modification—as to the necessity of rest in all cases of tuberculosis. If the rest in these cases is limited to the organs of digestion and to the proper regulation of the diet, then I agree with the Doctor; but the large proportion of cases is benefited by exercise in the open air.

Dr. SPIVAK of Colorado—I have little to say in addition to what I have already said. I am thankful to Dr. Tyson for taking up the defense. I read the paper not so much to relate to you the nine cases as to urge upon you the necessity of rest in these cases. I wanted to arouse interest in the profession to one of the best methods that can be used and one which nature employs to cure disease. I have been interested in this subject many months. I am sorry that the facilities of the library here does not permit of more extended research on this subject; there are only fifteen or eighteen papers or monographs in the whole literature on the subject of rest. I have not found one school that treats of the subject of rest in gastro-intestinal disorders. I have seen good results in many cases and in none have I seen any harm result. In regard to tuberculosis, I did not mean to say that all cases should be treated by rest in bed; I said that those cases that were suffering from fever should go to bed. My opinion is based upon a good many cases observed. They feel a great deal better in bed than they do after a walk. Every patient who has a fever, when he exerts takes something away from his strength. Furthermore, I stated that patients who suffered from diarrhea or vomiting should also go to bed. I limit these cases where rest in bed is indicated in tuberculosis where there is temperature, diarrhea and vomiting.

DILATATION OF THE STOMACH, WITH REPORTS OF CASES TREATED BY DIET, MASSAGE AND INTRA- GASTRIC ELECTRICITY.

Presented to the Section on Practice of Medicine at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY BOARDMAN REED, M.D.

PHILADELPHIA, PA.

There has been a tendency of late among writers to regard enlargements of the stomach as of little or no consequence, unless very excessive and complicated by such a degree of muscular weakness as to render the organ incapable of emptying itself at any time during the twenty-four hours. Some recent authors do not give any place to dilatation of the stomach as a distinct or separate entity, but describe it incidentally under the heads of motor insufficiency and obstruction at or near the pylorus, on the ground that it is a mere sequela or consequence of one of these. But, notwithstanding the high authority which exists for a contrary view, the writer insists that there is a normal size for stomachs as much as for hearts, and that any notable enlargement of either, plus decided insufficiency, constitutes dilatation. It is granted that it is not in either case a primary disease, and also on account of the enormously disturbing influence of unhygienic diet and dress, stomachs do differ very widely in size within so-called normal limits; but even the cases called megalo-gastria by Ewald, in which in consequence of excessive eating or drinking the stomach is often found twice the usual size without indigestion, are no more normal than are hypertrophied hearts in which the circulation is well maintained. The enlarged stomachs which have not yet dilated are, in fact, very frequently a cause of other pathologic conditions and of symptoms both direct and indirect, especially by displacement of the uterus.

But to follow up this line of discussion would lead too far afield. The object of this paper is to show

the amenability to treatment of a certain class of cases in which the stomach as a result usually of hygienic errors, often dating from faulty feeding in infancy, has become decidedly enlarged and weakened, cases, which while much less serious than those dependent upon pyloric obstruction, have been considered rather refractory to our usual therapeutic measures, if not quite incurable. The preponderance of such cases as well as of gastropotosis in women, even in young unmarried women in whom child-bearing can not be invoked as a cause, points to the probability that their mode of dress is a factor in the etiology.

Ewald² says: "I understand dilatation of the stomach or gastrectasia to be that condition of the viscus which is accompanied by the clinical symptom of disturbed gastric function due to the enlargement of the organ." This definition will answer perfectly well for the purposes of the present discussion.

Mathieu's³ division of atonic dilatation into "temporary" and "permanent" can not be accepted, since experience teaches that by our latest resources, including intragastric electricity and abdominal massage, with the help of diet, exercise, and in bad cases, lavage, all the atonic forms of dilatation can at least be greatly improved. The mildest cases and some of the worse ones, will often yield to diet and exercise alone. The more severe ones, including even those of long standing and those complicated by gastritis, will usually improve greatly upon a careful, non-fermentable diet,⁴ lavage, special exercises for strengthening the abdominal muscles and either massage of the abdomen or intragastric electricity, the choice being dependent upon the activity of the secretion of the gastric glands. Massage suits best when there is a deficiency of the gastric juice and is apt to aggravate when there is hyperchlorhydria, as pointed out in a previous paper by the writer.⁵ This aggravation is especially to be apprehended from a deep, thorough kneading.

Intragastric electricity in the form of a strong faradic current is very efficient in strengthening the weakened gastric muscle and in contracting the dilated organ. As mentioned by me in a former contribution, in which is described a new intragastric electrode,⁶ it will, in suitable cases, often cause a retraction of the lower border of the stomach to the extent of a full inch at one sitting, demonstrating beyond cavil that it does stimulate the gastric muscle directly, and in a most positive manner. Of this marked retraction each time only a small part persists, but in the pure atonic cases it has been usual to see a permanent gain of from one to two inches as a result of twelve to twenty treatments given from five to eight minutes at a time on alternate days. Some cases treated every day responded even more rapidly, but my experience points to the need of caution in this respect, as in some of my cases there was at the same time rapid lessening of HCl, and, later, after this had gone below the normal, there resulted nausea, loss of appetite, etc., from the further electric treatments, showing over-stimulation and depression of the glandular function.

On the other hand, in two cases of chronic gastritis with deficient secretion and enormous dilatation, similar treatment along with lavage, massage and the administration of HCl internally were followed by an increase in the amount of the secretion, at the same time that the stomach contracted. But

in these the gastric mucosa was manifestly less sensitive and could better bear the powerful direct stimulation required to contract the muscular walls. In one of these two cases the increase was temporary and the proportion of HCl declined again during the further treatment; in the other one a small family battery was used at the patient's house, not the stronger apparatus with high tension coil employed in my other cases.

I have not tried the experiment of giving small doses of intragastric electricity to increase the action of the glands, since abdominal massage and hydrochloric acid administered as a remedy are sufficiently effective for this purpose, and much pleasanter, but I do not doubt that faradism applied in this way would prove a safe glandular stimulant.

Fifteen patients in all have received intragastric electricity from me. Twelve of these had enlarged stomachs with more or less muscular insufficiency. One of those residing at a distance has received only two electric treatments at long intervals and no result in this case could yet be expected. In all the remaining eleven there has been a decided reduction in the size of the stomach, with an increase in the motility. In one of these, a case of hypopepsia with aggravated neurasthenia, the intragastric method had to be suspended at the end of a week on account of increasing nausea and anorexia. The various forms of electricity used externally, together with massage, being persevered with produced in this case results as favorable as were obtained in any of the others. The stomachs of several of the eleven are already normal so far as regards their size and motor functions. It will be of interest to add that eleven of the fifteen cases had either a normal or excessive secretion of HCl at the beginning of treatment by intragastric electricity, and that in nine of these a decided lessening of such secretion was noted by the end of two to four weeks. In one only of these eleven cases there was an increase of the HCl. In the eleventh case no opportunity has yet been offered for making a second analysis of the stomach contents.

The form of special exercise prescribed for most of my patients with dilatation of the stomach is the use of sets of the now familiar pulleys with elastic cords. I have found no other exercise, unless it be rowing, so useful in developing the abdominal and trunk muscles generally.

In the following reports one or more have been selected as specimens of each of a class of cases. These include:

1. Cases treated by diet and exercise, with in some instances tonic medication.
2. Those treated by the same methods plus massage.
3. Those treated by diet, exercise and intragastric faradism.
4. Those treated by the foregoing combination of remedial measures in addition to general massage, with sometimes very light effleurage of the abdomen, avoiding all kneading over the stomach. Lavage was added to the treatment in most of the cases in which there was much stagnation or chronic gastric catarrh. The diet has been shaped to suit the various indications present, especially the state of the gastric secretion. Particular care has been exercised to have the patients with atonic stomach walls avoid eating too large meals and to take never more than half a pint of fluid with each meal, including soup, but they have

been allowed, and, except in the worst gastrectasis, urged to drink water often between meals, though never more than one glassful at a time.

The great majority of these enlarged and weakened stomachs by the time they have come under methodical treatment have developed some degree of inflammation of the mucous membrane. One of the familiar types of chronic gastritis has been set up. More often than otherwise, as seen by me, the gastritis has been accompanied by either a normal or excessive secretion of HCl, and it is worthy of note that catarrhal inflammation with much mucus, rapid multiplication of bacteria, especially yeast fungi, and excessive fermentation, proves more difficult to overcome than the other morbid conditions. In other words, I have found it easier to strengthen and contract an atonic, dilated stomach and to relieve an accompanying hyperchlorhydria, when present, than to cure the coexisting gastric catarrh. One reason for this is that patients rarely are willing to continue treatment after they have ceased to suffer much inconvenience, and when both the motor function and the secretion of the gastric juice have been brought to the normal, the remaining catarrh usually produces few symptoms, though a low grade inflammatory process lingers. The patients considering themselves virtually well, abandon treatment and then, even if they do not drift back into their former faulty habits, as they are so prone to do, there is a tendency especially in those past middle age or at any age with poor reparative powers, for the remaining foci of disease to persist and to increase again upon the slightest provocation.

Case 1.—Lady, married, aged 45, has been under my care for the past year on account of chronic gastric and duodenal catarrh, with greatly deficient secretion of HCl and marked dilatation of the stomach, complicated by slight gastropnoia, and also by violent attacks of gastric pain. This case is fully reported in another paper to be read at the present meeting of the Association before the Section on Materia Medica and Therapeutics, but a brief account of it will be of interest in this connection. The patient residing at a distance from the city, in a town where there was no masseuse, and being unable to remain under my immediate care, the treatment was necessarily limited to diet and internal medicines mainly. She was required to eat moderate meals only, never overloading the stomach, and to avoid especially sugar, fried things, nuts, shell fish, except raw oysters, and hot or fresh bread. Her medication comprised HCl and pepsin on account of the marked deficiency of the gastric juice, and during part of the time small doses of nitrate of silver in pill form. She received no massage or intragastric electricity. By the end of a year the lower border of her stomach had retracted fully two inches at the same time that the proportion of HCl and of the ferments had returned to about the normal. Her painful attacks had also ceased to recur.

Case 2.—Unmarried lady, teacher, came under treatment in the autumn of 1897, complaining of chronic indigestion with almost daily vomiting and headaches. This case was referred to me by Dr. Samuel Bolton of Frankford, and is also reported in the paper above mentioned, to be presented before another Section at this meeting of the Association. The salient facts will be very briefly summarized here. Upon beginning treatment there was moderate dilatation as well as chronic gastric catarrh and hypopepsia. The lower border of the stomach was a half inch below the level of the umbilicus and the motility was poor. When she last consulted me, April 9, 1898, her stomach had retracted to within normal limits and the percentage of HCl and of the ferments was fully up to the normal. There had been no vomiting or headache for three months. The treatment had been diet, much the same as in Case 1, and the administration of HCl and pepsin mainly. She had also been taught to wash out her own stomach and had done this every day at first, and latterly two or three times a week.

Case 3.—A gentleman, aged 53, has been under observation off and on for the past four years. When he first consulted me he had some acid gastric catarrh, with occasional transient attacks of catarrh of the small intestine, and constipation. His stomach walls were very atonic and the organ extended to

the level of the navel, with weak circulation and neurasthenia. Diet and medication at first accomplished very little except to lessen the catarrh and resulting fermentation. During the past winter systematic autolavage was practiced by him for several weeks on alternate mornings, and by means of this, together with a judicious administration of a pill of extract of belladonna and extract of yerba santa (the latter being an excellent sedative apparently to all the branches of the pneumogastric) varied occasionally by giving full doses of alkalies, the catarrhal process was greatly benefited and the HCl secretion reduced to the normal at the same time that the stomach began to lessen in size. Massage, both abdominal and general, was then added to the treatment and continued almost daily for one month. Later the patient learned to massage his own abdomen, and has since continued it. His stomach is now (May 15) within normal limits, the lower border being fully two inches above the navel and no splash is obtainable, even after drinking a glass of water. Bowels moved now easily with gr. one-tenth of aloin. Exercise with the pulleys has been practiced though not very regularly.

Case 4.—Unmarried lady, aged 25, came under my care first in Atlantic City in the summer of 1897. History of some obscure stomach trouble for six years and for a year or more past patient has had dull pain and nausea nearly every day, coming on soon after eating with frequent attacks of severe gastralgia, and occasionally marked vertigo. She was plump, well nourished and of good color, in spite of extensive atonic dilatation and very aggravated chronic gastric catarrh. The upper boundary of her stomach was in the normal place while the lower border was three to four inches below the level of the umbilicus as shown by percussion, the splash and the gastroduphane. The stomach was never found empty except before breakfast and not always then. There were the usual signs of stagnation and excessive fermentation of food. Microscopic examination showed the stomach mucus to be swarming with yeast fungi. There were occasional attacks of acute intestinal catarrh, which yielded with difficulty, and always violent pelvic pain at the menstrual period. Large and repeated doses of anodynes had been required for the dysmenorrhea and often at other times for the gastralgia. The stomach was washed out and a strict diet was enforced. Intragastric electricity in the form of a mild galvanic current—M.A. 5 to 10, the positive pole inside and negative pole in the form of a large flat electrode placed over the stomach—effected more relief to the gastric pain than any other agency. But the relief was temporary. The stagnation and excessive fermentation in a very largely dilated stomach were clearly the chief causes. Finally lavage was regularly employed and the high tension faradic current in as strong dose as could comfortably be borne, was used on an average every second day for at first ten minutes at a time, but later on, this dose having seemed excessive, the time of each sitting was limited to five minutes. There had never been any free HCl in the stomach since the patient had been under observation, though the T.A. an hour after a test breakfast was usually 50 to 60, representing largely fermentation products. After the intragastric faradism had been continued for several weeks a trace of free HCl once appeared in the gastric contents, but none has ever been found since.

Under this energetic treatment, continued more or less regularly for three months, the stomach walls gradually contracted and now the lower border is just above the level of the umbilicus. There was, however, during the latter part of the time that the intragastric faradism was being used regularly, a loss of digestive power and a return of nausea, vomiting and dizziness, symptoms which had previously troubled her much, but had been greatly relieved by lavage and restricted diet. During the last two months the latter measures have been relied on chiefly, with some help from external electric applications, and the patient, while retaining the gain in the size and motility of the stomach which the intragastric faradism helped to effect, is continuing to make satisfactory progress in other ways. There is no more nausea, less dizziness, and greatly less gastric pain, though there is still some mucus secreted daily in her stomach. A highly nervous temperament has complicated the case, and lack of means to obtain massage treatment has been an unfortunate embarrassment. A retraction of fully three inches in the size of such a seriously dilated stomach is, however, a striking evidence to the power of intragastric faradism in such cases.

Case 5.—Widow; aged 64; resident in a neighboring city; came under treatment Oct. 13, 1897, with complaint of cardiac palpitation and flatulent dyspepsia, dating back a year or more. She had been troubled much longer with constipation and occasional headache. A strong, active, energetic and well nourished woman, weighing 150 pounds, she complained of a painful dragging in the abdomen in walking, especially in going

up-stairs. Examination revealed an exceptionally sound, strong heart of normal size, with normal lungs and liver, and kidneys not displaced, but her stomach was enlarged from the usual level above to three and a half inches below the umbilicus. The usual tests showed only a little motor deficiency, and a small, mixed meal would leave the stomach in four to five hours, yet there was an abnormally loud and large splash after drinking a glass of water, and this together with the sensation of weight and dragging after meals, pointed to the fact that the enormously enlarged stomach was not in a proper tonic condition as to its musculature, or to use the cardiac phraseology, that there was hypertrophy, with some dilatation. The analysis of the stomach contents revealed marked hyperchlorhydria and a large amount of mucus with other signs of chronic acid gastric catarrh.

The treatment at first consisted mainly of remedies to reduce the hyperchlorhydria, and simple, plain diet, as little fermentable as possible, with lavage when she could come to the office, which was only at long intervals. Later she came to the city and began a more systematic treatment. Intra-gastric faradism was now given on alternate days—sometimes every day—with the result of rapidly contracting the stomach. The action on the glandular function was less favorable than in any of the other cases. When the sittings were daily for five minutes during one week, there was a decided increase in the percentage of free HCl, the only instance in which this resulted, in my experience, in a case of hyperchlorhydria. There was also nausea after the latter treatments. Massage was thereupon ordered instead. This was given vigorously over the body generally, but very lightly over the abdomen—little more than effleurage. Lavage was also given every morning for a while, and later every other morning before breakfast. The hyperchlorhydria was not reduced so readily as usual, requiring a pill of belladonna and yerba santa to be continued for some time before coming under control. The lower border of the stomach now, May 15, is one inch above the level of the umbilicus, when the patient stands after drinking a glass of water. This is a reduction in size of over four inches. The gastritis is also greatly improved. The patient is still under treatment.

Case 6.—Widow; aged 38; has been for years a sufferer from indigestion and neurasthenia, dependent upon acid gastric catarrh, dilatation of the stomach and a right floating kidney. There has been a remarkably relaxed condition of her tissues in all parts of the body, and yet singularly, she is almost the only lady patient seen by me with a marked dilatation of the stomach (or with gastroptosis) who has not had at the same time a displaced uterus. She had been under the professional care of various specialists on account of these ailments. During the past year and a half she has consulted me with more or less regularity. In the winter and spring of 1896-7, she made some little favorable progress as a result of diet, physical culture, massage, occasional lavage, and treatments by galvanism to the spinal and abdominal centers. But she returned to her home in a distant city during the summer, and while there suffered quite a relapse. December 10, 1897, intra-gastric faradism was begun and given, as a rule, three times a week till April 11, 1898. Massage was continued meanwhile daily, but by an unskilled attendant, and lavage was given two or three times a week. When the intra-gastric electricity was begun her stomach extended from the normal position above, to three and sometimes four inches below the level of the umbilicus. During the first three months of this treatment there was less improvement than in any of my other cases. The lower border of the stomach was still below the navel; but on persevering another month with all the measures and in addition administering full doses of a compound containing nucleo-albumins and bone marrow, she began to improve more rapidly. Now, the lower boundary of her stomach is one inch above level of the umbilicus, and she is stronger and better than for several years.

The percentage of free HCl, formerly a little excessive, has been lowered somewhat below the normal, but there has been no nausea or other noteworthy disturbance of digestion by the unusually long treatment of intra-gastric electricity.

There have been conflicting reports from other observers as to the effects of intra-gastric electricity, both on the muscles and glands of the organ. One denies that contractions of the stomach walls can be produced in this way. My cases, 4, 5 and 6 above reported, are therefore of especial interest taken in connection with the preceding summary of the results in all of the fifteen cases in which I have em-

ployed direct electrization of the stomach. They certainly establish beyond further question the fact that the motor function of the stomach can be powerfully stimulated by this means.

As to the effect upon secretion, the results above cited seem to indicate that this probably depends upon the dose and upon the degree of reaction. In the dose of faradism necessary to produce efficient muscular contractions there resulted in all except one of the cases with a normal or excessive percentage of free HCl, a depression of the secretion. In cases of gastrectasia with chronic gastric catarrh and very deficient secretion, it agreed better than in most of the others, and in one of these, not reported here in full, the current from a cheap family faradic battery, with a coil of coarse short wire and not very rapid vibrator, applied through the intra-gastric electrode, seemed to help materially, along with massage, lavage, etc., in restoring the lost function of the glands, as well as in contracting the seriously dilated stomach. It is probable that the very slowly interrupted faradic current would effect contraction in this way with less risk of over-stimulating the glands, and I shall try this in my next suitable cases.

Too much emphasis can scarcely be placed upon the importance of these comparatively simple and safe methods of curing or ameliorating atonic dilatation of the stomach. Large numbers of persons suffering from this serious condition are permitted to go without any efficient treatment, while others are submitted to the new surgical operation known as gastrorrhaphy or gastroplication, designed to reduce the size of the viscus. This may be necessary in extreme cases, but surely all other practicable means of relief should first be exhausted.

THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE DUODENUM BY DIRECT METHODS.

Presented to the Section on Practice of Medicine at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June, 7-10, 1898.

BY FENTON B. TURCK, M.D.

CHICAGO.

The use of the gyromele in the diagnosis and treatment of intestinal diseases is now so well known by the profession that it would seem hardly necessary to describe the method, but as more work is being accomplished and new facts learned it is destined to add to our knowledge of the physiology and pathology of the gastro-intestinal tube. The gyromele as made for diagnosis, and treatment of the esophagus, stomach and intestines is modified for each part of the alimentary tube to which it is applicable, and also for the various kinds of uses in both diagnosis and treatment. The gyromele as is well known is composed of three essential parts. The cable with a spiral attached to one end and to the other end is attached an instrument for producing revolutions of the cable and spiral. To the end of the spiral is attached a

sponge or bulb or both as required. The cables are made of different lengths and degrees of flexibility adapted for either the esophagus, stomach or intestine. When used for sounding the esophagus short cables Nos. 1 and 2 of 60 to 70 cm. in length and of 2 degrees of flexibility are used.

The spiral attached to the end is short, ending with a bulb or sponge as the conditions of the case require. Various sized bulbs can be attached as in ordinary esophageal sounds. The principal advantage found in this instrument is that the revolving sponge when it passes into the stomach can be palpated upon the abdominal walls, proving that it has passed the cardiac orifice. It is for this reason that the gyromele with a long cable and spiral 120 cm. (or longer) is of such value in passing through the stomach and pylorus into the intestines that in palpating the revolving sound upon the abdominal walls, we gain positive knowledge in locating the viscera. By aspirating through the tube which covers the cable we can obtain the contents and reach the parts safely under the observation of the palpating hand. The vibrations may often be seen as well as felt and by the introduction of water or air or both reach a confirmation in diagnosis that could not be accomplished by any other way, and further, we are enabled to carry out a line of treatment by direct methods.

Kuhn has recently devised an instrument for sounding the stomach and duodenum, but this is simply a modification of the gyromele. Hemmeter has devised a method of ballooning the stomach and passing a tube along the upper borders of the inflated bag within the stomach. This method I have not had any experience with but it appears to be ingenious and of practical value. In the *Centralblatt für Innere Medizin*, No. 9, 1898 (Turck, Die Priorität der Sondierung von Oesophagus, Magen und Eingeweide mittels der Gyromele, biegsamen Revolversonde), I have given the literature on sounding or intubation of the duodenum.

Method of Introduction.—The cable enclosed in long rubber tube is passed into the stomach in the same manner as in the introduction of the ordinary stomach tube. When the stomach is reached the revolving apparatus is attached to the outer end of the cable, and revolutions are produced. The vibrations of these revolutions are palpated upon the abdominal wall and as the gyromele is pushed along the greater curvature it reaches the pyloric end of the stomach, which may be indicated upon the abdomen by outlining with a pencil. By carefully pushing the instrument further an obstruction may be observed which after a moment's delay will disappear and allow the end bulb to pass through the pylorus into the duodenum or further into the jejunum. In case there is much retching or contraction of the abdominal muscles the end bulb and spiral may be deflected across the antrum pylorica, and reach the lesser curvature instead of passing on through the pylorus. This may be detected by palpating the revolving sound. The instrument may then be slightly withdrawn and under the palpating hand pushed onward again until the pyloric orifice is reached and then pass into the intestine.

Method of withdrawing contents and introduction of air or water into the intestines.—When it is desirable to aspirate fluid from the intestine the upper end of the tube is closed by a rubber cork through which the cable passes and is thus made air-tight. To

the side of the rubber tube is attached a small tube, through which the fluid may be aspirated. The contents thus may be used for chemic analysis and microscopic examination. When desired fluid or air or both may be forced into the intestine and by inspection, palpation and percussion location can be confirmed. When water is thus forced into the duodenum another tube can be passed into the stomach. If no fluid is found there then aspirating the fluid back from the intestine through the gyromele will give further positive evidence that the pylorus has been passed.

Treatment.—The gyromele is used in the intestines for similar therapeutic purposes as in the stomach. 1. The massage of the revolving sound produces an effect upon the entire vascular system supplying the intestinal walls. By the reflex action of the vasomotor system of the splanchnic area is stimulated, not only through the massage or rubbing effect but the vibratory effect can be distinctly felt and has been observed experimentally upon dogs, their abdomen exposed, and during laparotomies upon the human subject, in which the changes in the circulation can be distinctly seen. This has been previously reported by the writer and others. 2. Cleaning the mucous membrane by removing the adherent material with the revolving sound and green soap, then washing out this loosened slime (decomposed remnants of food, necrosed and degenerated epithelial cells and other irritating material) originated with the writer and is unquestionably of the greatest value in treatment. 3. The application of antiseptics or other medicaments can be resorted to by topical or direct methods with exact dosage, such as the use of nitrate of silver, formalin, etc. The entire mucous membrane may be coated with bismuth when desired. 4. The use of the gyromele as an electrode is superior to other electrodes because the revolving sponge can be located anywhere over the abdominal wall and the application of electricity can thus be made at will to any desired part, as for instance, in cases of patulous pylorus. The electrode may be inserted at the orifice and the faradic current used, or if indicated it can be passed on into the duodenum for the treatment of atony and vascular disturbances.

It is not possible in all cases to pass it into the duodenum; benign and malignant tumors of the pylorus when complete may obstruct, or severe spasmodic forms of stricture. The value in diagnosis is of similar importance to the esophageal sound in strictures of the cardia. In cases where there is much vomiting and retching which may become so violent as to defeat the attempt at passing the sound, then the examination may be postponed for a day or so, when on another attempt it will be found that the sound may be introduced. The contraindication for the use of the gyromele are the same as those of the stomach tube.

In conclusion I wish to particularly call your attention to the diagnostic as well as curative possibilities of the gyromele in an hitherto unexplored field, and doing away partially with the exposure of our patients to the risks of the exploratory laparotomy, which has become such a fad in the past few years, for all affections of the gastro-duodenal region which do not readily yield to medicinal treatment. By means of it (gyromele) we can with almost certainty diagnose an obstruction at the pyloric orifice or a relaxation of the same; we can enter the duodenum and apply our medicaments as called for; we can obtain the various speci-

mens of the contents (food, etc.) for chemical, micro- as well as macro-scopic examinations and determine positively whether or not we are dealing with a pathologic condition of the stomach or of the duodenum.

For want of time the cases will not be presented here but will be published later with a full report.

CHRONIC DIARRHEA ASSOCIATED WITH ACHYLIA GASTRICA.

Presented in the Section on Practice of Medicine at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY ALLEN A. JONES, M.D.,

ADJUNCT PROFESSOR OF MEDICINE, UNIVERSITY OF BUFFALO, BUFFALO, N. Y.

Among the causes of diarrhea the different conditions of the stomach that give rise to abnormal intestinal fermentation and irritation are of the utmost importance. For many years a form of diarrhea termed *lienteric* has been described as being characterized by evacuation of the bowels immediately following each meal, the stools containing considerable undigested food. Sometimes more than one movement follows a meal. The explanation given for this a few years ago was that the food was hurried through the gastrointestinal tract with such velocity that there was no time allowed for its digestion. While such an explanation is in part true it does not cover the phenomenon properly, nor satisfactorily account for the hurried peristalsis. It was advanced by some that the food eaten for dinner, for instance, was partly passed from the rectum immediately after that meal. It may be readily understood how this hypothesis was necessary to account for the undigested condition of the food in the fecal discharges, but no thought was had of the state of the gastric or intestinal digestive secretions. It was not until the gastric secretions were studied, and somewhat more known of the motor functions of the stomach, that a better light was thrown upon this affection. While it will be readily admitted that only a part, perhaps a minor part, of digestion is carried on in the stomach, yet it will be also confessed that the passage of much unchanged food from the bowels will not be likely to take place if the retention function of the pyloric sphincter is normal, and if concomitantly there exists an active secretion of gastric juice. That this position is quite tenable is well illustrated by the fact that it is very seldom a diarrhea is observed to be *lienteric* provided the gastric function is correct. There may be, and there often are, cases of more or less persistent diarrhea associated with a good condition of the stomach, but such cases do not usually present the characteristics of *lienteria*.

When mixed foods are retained long enough in the stomach, and the chemical and mechanical changes incident to digestion in that organ proceed actively, the food is in a fair state of solution and comminution, and will not likely pass through the small intestine without being so changed that separate food elements will for the most part have become unrecognizable. If gastric secretion were normally active, and yet the pylorus were abnormally relaxed and patulous, food might be so hurried into and through the intestines as to appear unchanged in the feces, but such a state does not frequently exist, as the pylorus is exquisitely sensitive to active secretion, and the circular fibers are stimulated reflexly to prop-

erly protect the orifice and prevent the stomach emptying itself in undue haste. On the other hand, if the gastric secretions fail and the gastric contents are not digested, whether they remain in the stomach a long or a short time, we have the most apt condition of affairs to give rise to *lienteric* diarrhea provided intestinal peristalsis is sufficiently hurried to prevent complete intestinal digestion, or provided the *succus entericus* is diminished or absent.

In the gastric affection named by Einhorn "*Achylia Gastrica*," there exists a suspension of the secretions of the stomach, in some cases as the result of atrophy of the gastric glandules, in others as the result of a nervous disturbance of secretion. It is probable that all cases of this affection do not arise from glandular atrophy. For some years Stockton has maintained that the disorder often begins, and may continue, as a neurosis, and he has found a special form of ocular refractive error associated with it. In writing upon "*Gastric Anacidity*" some years ago I also emphasized the suggestion that some cases perhaps commence as a neurosis and may go on to subsequent organic disease and atrophic changes. Be that as it may, when the disease is once established the stomach is practically useless so far as chemical change of the food is concerned. Finely divided, thoroughly masticated carbohydrates may undergo more or less digestion, but albuminoids are not changed. A remarkable absence of fermentation is observed in the stomach in this condition wherein there exists a state of affairs, one would say, should be well calculated to encourage fermentative and putrefactive changes.

As is now well known, but little acetic or butyric acid is ever formed, even when much saccharine, starchy and fatty food is ingested. Even in cases with poor gastric motricity and consequent delay in the passage of the contents into the duodenum, there is yet practically no fermentation. This is the opposite of conditions prevalent in cases of *gastrectasia* and food stagnation from pyloric stenosis or in atonic dilatation.

It should not be understood from what has just been said that food stagnation is never accompanied in these cases by putrefactive changes, as sometimes no doubt actively toxic substances are developed. However, the point it is desired to emphasize is that symptoms of disturbance of intestinal digestion seem more troublesome and pronounced in cases of *achylia gastrica* than direct symptoms of the disordered gastric condition.

As to the causes of diarrhea in cases presenting an absence of gastric secretion, they may be various. One of the most important factors is the precipitate manner in which the stomach propels its contents into the intestine in a large proportion of cases. It is sometimes found that the stomach is empty one hour after a full meal. In some of Dr. Stockton's cases complaining of no gastric trouble, but seeking advice on account of persistent diarrhea, this hurried emptying of the stomach was discovered. The chronic inflammation of the gastric mucosa may extend into the intestines and thus give rise to diarrhea from chronic catarrhal enteritis, or the intestine may simply rebel from overtaxation, and by way of self-protection expel its contents at the earliest possible moment, or the diarrhea may be the result of intestinal irritation from unusual toxic substances developed in the bowel. Hemmeter found normal pancre-

atic and hepatic secretions in five cases of achylia associated with diarrhea, and thinks therefore that extension of the inflammatory process from the stomach into the intestine is probably not the cause of the trouble. He mentions Oppler's report of a number of cases of diarrhea dependent upon loss of gastric secretion, and also Biedert's account of his own case, which is a striking illustration of the relation of one affection to the other. The diarrhea differs in different cases. For instance, in some there are invariably several morning evacuations, and after the middle of the forenoon there is no further trouble; while in others the diarrhea is post-prandial, one or more stools occurring soon after each meal; and in a third set of cases there are many evacuations during the day, taking place irregularly and not following any fixed rule. In these cases there is diarrhea every day; but there is yet another class in which looseness of the bowels is periodic, coming on suddenly, lasting a week or two and being succeeded by constipation or in some cases by regular normal daily evacuations for a short period which is followed by another attack of diarrhea. The looseness of the bowels is chronic, as illustrated by a number of our cases having had the trouble for years. In some instances a great deal of intestinal flatulency is complained of and a large quantity of gas is expelled at stool. Pain is not a common symptom in these diarrheas. There may be occasionally some colic, but as a rule it is not at all pronounced. There is usually no elevation of temperature; it is an afebrile condition, the temperature is sometimes below normal. The appetite in some of these cases is voracious, approaching indeed what might at times be dignified by the term bulimia. The character of the stools varies. In few instances is there an abnormal amount of mucus. The discharges are frequent and watery, and contain undigested food, their features being modified by temporary influences. In some cases we have observed constipation. Einhorn says there is no rule, but that either diarrhea or constipation may be present.

In the treatment of this type of intestinal affection a few drugs are in some cases most efficacious. The first and most valuable is hydrochloric acid. It is our custom to give 20 to 30 drops of the dilute acid after meals, and see that the dose is repeated in an hour. This remedy seems a positive necessity for these cases. It is the habit of some clinicians to administer it before meals in large doses, say four to eight c.c. well diluted, in deference to Jaworski's statement that the acid is needed to develop the formation of pepsinogen in the gastric glandules. D. D. Stewart recommends the use of the remedy in this manner. The acid is quickly neutralized and combined in these stomachs. I have repeatedly failed to detect its presence as early as ten minutes after its administration; indeed, after meals it has been necessary to have the patient take good sized doses several times, and then to give him an extra 30 drop dose in my office, five minutes before withdrawing the contents of the stomach in order to find a small amount of the free acid present. Another remedy that has proven useful, and which may be given with the hydrochloric acid, is the tincture of the chlorid of iron. Usually it is not necessary to give large doses, five drops being quite effective. In one case excellent results were obtained by adding two drops to every glass of water that was taken. If small doses fail to control the diarrhea, larger should be tried

before the drug is abandoned. Bismuth preparations have not proved of much use in our cases. They may, however, be of service when the intestinal mucous membrane is the seat of considerable irritation and catarrh. When an excess of indican is found in the urine, benzosol, benzonaphthol, ichthyol, ichthalbin, salicylic acid, salol, or other intestinal antiseptics may be administered, though small doses of calomel will usually cause a prompt disappearance of the indican.

As there exists in these cases what D. D. Stewart has so well characterized "a suspension of the gastric secretory function," it is advisable to give pepsin in addition to the hydrochloric acid; indeed, this is one of the few conditions that call for its exhibition. Sometimes small doses of Fowler's solution, according to the old plan, given immediately before meals, seem efficacious. In some cases I have remarked benefit following the use of small doses of a combination of arsenic, gold and the red iodid of mercury. Intra-gastric faradization has been of signal service in several of our cases; the retentive function of the stomach having been manifestly and promptly improved, probably by the effect of the electricity upon the circular fibers at the pylorus.

DISCUSSION.

Dr. J. M. ANDERS of Philadelphia—It is with pleasure that I listened to this paper dealing with two interesting and important conditions in association. I believe that achylia gastrica occurs most frequently in gastric carcinoma and atrophic catarrh of the stomach and neuroses of the stomach as he has intimated. I also meet with this condition in lenteric diarrhea. I believe lenteric diarrhea is more frequently dependent upon catarrhal states of the intestines than any other factor. To corroborate this view I frequently find more or less mucus in the stools. I was somewhat surprised not to hear that this condition of achylia gastrica has not been found associated with tuberculosis; on the other hand, a number of cases of tuberculosis associated with diarrhea—of lenteric character—have been met with. I believe that in the majority of cases some great underlying condition co-exists, tuberculosis, amyloid degeneration, stomach neuroses, etc., which should not be overlooked in the treatment of this affection. I agree with the treatment as described by Dr. Jones. This is one of the few conditions in which large doses of hydrochloric acid and pepsin are necessary.

An interesting thing from a scientific point of view that I have noticed is that in certain conditions where has been found, by the use of Ewald's test meal, an absence of hydrochloric acid and the gastric ferments in the gastric contents, that in spite of the absence of these associated constituents, there may be perfect intestinal digestion and absorption. I have seen two such cases not long since and also have read an article on this same subject.

Dr. STOCKTON of Buffalo—Dr. Jones has given us a good description of achylia gastrica in association with lenteric diarrhea. In my judgment we should separate these cases into two classes—first, those which are accompanied by intestinal disturbances, and second, those which are not so accompanied. No doubt the advent of diarrhea is an unfortunate factor in patients suffering from achylia gastrica, yet when diarrhea does not exist there is a retention of food. This peculiar symptom of achylia gastrica—diarrhea—does not depend upon one factor alone. It is largely a nervous expression. I mean to say that undoubtedly some cases are associated with atrophy of the gastric mucosa or catarrh; these cases should be recognized. On the other hand, we have cases not associated with either catarrh or atrophy of the gastric mucous membrane. These cases have periodical attacks which lighten up without any apparent cause. I have one patient who has this trouble only when pregnant; I have followed her through three pregnancies; the woman is today as well as she was ten years ago. Another patient of mine always has this diarrhea when at home; as soon as she goes away from her home she is relieved. I believe that we have certain cases of achylia gastrica dependent upon nervous conditions alone; we also have them as the result of atrophy of the gastric mucosa. When this is the case they should not be considered as typical achylia gastrica.

Dr. ELLIOTT P. JOSLIN of Boston—This paper has been one of interest to me, coming as it does from one so intimately connected with the study of this disease. Dr. Jones has placed a special emphasis on the symptom of diarrhea in achylia gastrica. It is interesting that its opposite—constipation—is perhaps quite as frequent. This is to be expected when dealing with an affection of largely a functional origin. Rosenheim pointed out in his Moscow address, it is the variability of the symptoms at different times in the same individual that stamps the nervous dyspeptic. One of these cases of achylia gastrica with constipation I recently saw with Dr. James J. Putnam. It deserves mention because the patient presented a triad of symptoms which I believe will be found quite commonly in the future. The patient was a tall, spare man of 71, a captain of a coasting vessel. He was never immoderate in the use of food or drink. Four years ago, following what was supposed to be an attack of the gripe, he developed melancholia, and on account of this sought Dr. Putnam's advice. In the course of the examination a complete enteroptosis was discovered. The lower border of the stomach, when distended with air, was at the pubes, while the upper, in the upright position of the patient, was at the umbilicus. The liver and kidneys were correspondingly depressed. But Stiller's sign, "movable tenth rib," was absent. Repeated examinations showed complete absence of free and combined HCl and peptones, thus giving us in addition to the melancholia an enteroptosis, achylia gastrica. Are not the parts of this triad melancholia, enteroptosis and achylia gastrica, simply different expressions of a disturbed mechanism?

In the treatment of this affection I can hardly agree to what has been said as to the use of HCl. My own notion was that if a nurse gave a patient, by mistake, fifteen drops of dilute HCl before a test breakfast, the test for the free HCl in the stomach contents removed one hour later would be of no avail. I am indebted to Prof. Ewald for pointing out to me my error. Some experiments of Prof. Chittenden, recorded in his book, "Digestive Proteolysis," give the explanation. To put the matter in a popular way the albumin in two or three eggs dissolved in a little water, will combine with a pint of .2 per cent. HCl, and the solution when then tested with Günzburg's reagent will fail to show even a trace of free HCl. The few drops of acid which we give a patient are simply a "drop in the bucket," and are combined with albumin and still more with peptones the moment they reach the stomach. It is practically impossible to give the needed amount of HCl in these cases. Pepsine would be an advantage in achylia gastrica if we could give a sufficient amount of acid to insure its action, but we have seen that it is impossible, and consequently pepsine can be of no use save for its mental effect on the patient. If one feels constrained to give a ferment, then give pineapple juice, as that will digest albumin in a neutral, acid or alkaline medium.

What then, shall we do in these cases? The stomach does not digest food, therefore the food must be gotten out of the stomach as soon as possible. Fortunately, nature does this for us as a rule. If she does not there is *nux vomica* to fall back upon. What next? The food must be given in a state to enter the intestines without further change. Finally, the recent operation of gastrostomy shows that patients can get along without a stomach, but we know they can not get along without food. An abundance of easily assimilable and nutritious food is the key to the successful treatment of achylia gastrica.

Dr. BRIDGES of Nebraska—In regard to the point made by Dr. Stockton in cases of associated diarrhea in achylia gastrica, one must remember that this condition may be, and frequently is, an independent affection of the intestines. Most authorities give constipation instead of diarrhea as existing in this condition as a rule. Achylia gastrica in most cases leads to a condition of dilatation or a condition of stagnation; we also have in many cases of achylia gastrica vomiting associated with constipation. A condition of catarrh of the duodenum or small intestinal glands giving rise to diarrhea is quite plausible. The frequent taking of certain food gives rise to irritation of the small intestine, with accompanying diarrhea. If some cases depend upon a neurotic condition there is always a possibility of a chance for improvement and possibility even for cure. I am especially interested in this subject, especially after reading the writings of Einhorn where he states that the repeated examination of the stomach contents show an absence of the stomach secretions, and even of the rennet ferment. To me there is no doubt but that there is an atrophy of the gastric follicles.

In regard to the treatment, what I would do in these cases would be to employ gastric faradization before employing medical treatment. In one case I carried out intra-gastric far-

dization for a period of two months with great improvement in a young girl. This treatment should be carried out two or three times weekly.

Dr. ALLEN A. JONES, in closing—Dr. Anders has mentioned the dependence of achylia gastrica upon tuberculosis. It has not been our experience to find it associated with pulmonary tuberculosis, but rather in this condition have we found catarrhal gastritis with diminished secretion of gastric juice.

Dr. Joslin has pointed out that the great desideratum in these cases is that the stomach should empty itself very soon after eating; and he also doubts the efficacy of hydrochloric acid in the treatment of the affection. While I agree with him as to the truth of the theoretic reasoning, clinical experience has taught me that these cases feel badly and have diarrhea whenever the stomach empties itself with great haste and whenever they cease taking hydrochloric acid.

HEMOGLOBINURIA AND HEMOGLOBINEMIA. REPORT OF CASES, TWO DEATHS AND FOUR RECOVERIES.

Presented to the Section on Practice of Medicine at the Forty-ninth Annual meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY GEORGE J. HIRTH, M.D.

PROFESSOR OF HYGIENE AND ASSISTANT TO CHAIR OF MEDICINE, MILWAUKEE MEDICAL COLLEGE,
MILWAUKEE, WIS.

Hemoglobinuria, which may be a disease *per se*, is also present as a symptom in many other conditions, viz: in various chemical intoxications, a long list of infective processes and also extensive burns; more especially does it occur, as a disease, in paroxysmal hemoglobinuria, syphilis and malaria being the cause. A given predisposition, combined with a sufficient cause, as sudden exposure to cold, strained physical condition and the like, will produce the characteristic lesion which is to be found in the blood, and which consists of the disassociation of the oxy. or carbon-dioxy hemoglobin, the free hemoglobin being taken up by the blood plasma—hemoglobinemia (Virchow). The free hemoglobin produced by the increased hemolysis is eliminated as such, in part, by the kidney (hemoglobinuria), and in part as gall (bile pigment of bilirubin and biliverdin). The stroma of the blood corpuscles having undergone this change are to be found generally in the blood or urine a short time thereafter as *blood shades*.

In consequence of the above, there will be an elevation of temperature, enlarged spleen and liver, more or less icterus, and urine containing a high percentage of hemoglobin with possibly gall pigment and few or no *blood shades*.

The cases which I am to report may be known as group 1, patients A, B, C and D. and group 2, patients E, F and G, and before describing each case a few introductory remarks regarding group 1, as regards pre-existing conditions, will be seen to be pertinent.

Group 1: four men, A, B, C and D, painters, engaged in shellacing large beer vats for several seasons past with seeming impunity, three of whom, while working under about the same conditions, on or about January 26, and working until about seven o'clock, after which they went in seeming good condition to their respective homes, were taken ill: A, late that night, and B, the following day, both making their *exilus* within twenty-four hours after they had concluded their work on the previous day. Patient C recovered after a serious illness of several weeks, having gone through similar prodromal symptoms to those who died. A history and detailed account of symptoms of surviving patient C are as follows:

Patient C, age 26 years, weight 185 pounds, of good

family history, engaged in shellacing for several seasons, suffered in common with deceased patients A and B, at various times during several weeks prior to his illness, with nausea, headache, muscular weakness, prostration, ringing of the ears, mental impressions of exhilaration, and temporary attacks of aberration of the mind, with mental depression and sharp, shooting pains, mostly in the back—*sordes labialis* also quite extensive. On Friday evening, Jan. 28, 1898, after having worked till seven o'clock this same day, this patient consulted me for the above described symptoms, and on the following morning I was called to my office to care for patient, whom I found greatly prostrated, with pulse slightly accelerated, temperature 99.6, respiration decreased, pupils partly dilated, slightly cyanosed condition of the lips and finger tips, cheeks slightly flushed, and physical and psychological conditions of patient much involved. When patient attempted to leave he staggered and fell, there being complete inability to walk other than in a tottering condition. Patient was taken to his home and prescribed for as follows: Pills containing 3 m. of digitalis, 3 m. of strophanthus and 1/100 nitro-glycerin; one every three hours, and two tablespoonfuls of lime water every one and one-half hours, placed in a warm bed and surrounded with warm water bottles, and given a cathartic. Several calls were made during the day, and at ten o'clock in the evening patient assumed a comatose condition, countenance became from white to pale livid; respiration deep and labored, 9 per minute, and pulse between 40 and 45; extremities, nose and ears, cold and clammy. On the fourth day I found the liver and spleen much enlarged, the latter being from three to four times its normal size. Cold water was used freely on face and chest, strong, hot coffee was given after thirty minutes, when patient was brought to a semi-conscious condition. He was given a large enema of three quarts of cold water, and a great quantity of putrid fecal matter was passed, and the enema was repeated with same result. Patient remained unconscious and had no account of time for the first four days of his illness. I catheterized and drew off 1½ pints of dark to reddish-brown urine, which, upon examination the following day, contained hemoglobin. Guaiac turpentine test, giving an indigo-blue ring and an absence of blood corpuscles by microscopic examination. I found bile pigment on the third day, and it disappeared on the ninth, a small amount of albumin and a few blood shades, and no sugar.

On the second day of the patient's illness, symptoms, circulation and respiration were improved, but the central nervous system became more involved; the skin and conjunctiva became tinged with yellow; complete loss of vision, pupils completely dilated and did not react to the most intense light. Patient was kept in a dark room, eyes washed with a solution of Seyler's tablets and dressed three times daily. At the end of the fourteenth day patient began to see the larger objects in the room, such as sofa, bureau, etc., but could not count fingers at normal distance.

On the eighteenth day an ophthalmoscopic examination was made by Dr. Bartlett, professor of ophthalmology of Milwaukee Medical College, which revealed the fact that the retina was immensely congested, there being about eight to ten times the normal amount of capillaries; pupils did not respond to light, and there was a general congested condition of the eye and its appendages, with a few unaccounted

for spots in the retina. At present the vision has improved to a considerable extent, though subnormal.

On the second day patient lost control of his extremities and back, having interrupted ringing of the ears, dizziness and a train of nervous symptoms which I shall omit, and was first able to get out of bed with assistance on the twenty-first day after onset of disease.

Pustular macules significant of chronic pyemia began to appear on the seventh day in great numbers all over the body, but particularly about the face, and from that time on I opened from fifteen to thirty daily, being in full bloom of pustulation; they continued for forty days, at the end of which time a picture was taken and an actual count made, giving 131 macular lesions in one or the other of their characteristic stages, on the face alone. From this time on they began to abate considerably, with return to the normal condition of the blood.

On the twenty-first day of the disease an examination of the blood was made by Dr. Evans, with the following results: Poikilocytosis; failure to form in roulettes. Percentage of hemoglobin, .80. Number of red cells per c.m., 3,072,000. Percentage of normal, 61.44. Corpuscle index, 130. Number of white cells per c.m., 8400. Percentage of normal, 84.

Reported examination of the blood showed an increase to normal constituents until the eleventh week, at which time it was practically normal.

The pathologic findings in the urine disappeared in the following order, viz: hemoglobin was absent on the third day, bile pigment was found last on the ninth day, and the last trace of albumin disappeared on the eleventh day; spleen began to decrease in size on the twelfth day; on the sixth or seventh day the *sordes labialis* began to disappear, and the appearance of a small open sore became manifest on the left side of lower lip, and took on a very rapid growth; blood plasma constantly exuded at this point of lesion, and within fourteen days it appeared to be a typical rapidly-developing epithelioma. I considered it a dangerous factor on account of its very rapid development, and that it was due, doubtless, to the lessened cell-resistance, conjoined with increased cell irritability. Owing to the impoverished condition of the patient's blood I deemed it advisable to operate at once without an anesthetic, which was done by Dr. Earles and myself, at Trinity Hospital, on March 12, being about forty days after the first appearance of the growth. Operation a success. Microscopic findings proved it to be a true epithelioma. The report of Dr. Evans of Columbus Medical Laboratory, on same, is as follows:

"The specimen is a very pretty illustration of progressing epithelioma. You will never find a better illustration of invasion of underlying tissue than is here shown. There are no pearls or other phenomena indicating any disposition to degeneration. There is considerable ordinary inflammation."

The general tonic treatment of quinin bi-sulphate, alcohol, arsenic, iron, manganese, and faradization and galvanism, from 1 to 1½ milliamperes, to the spine and muscles was continued, and patient from this time on made a very rapid recovery.

Patients A, B and C, were quite temperate, but patient D was addicted to the free use of stronger spirits, and, while having suffered some of the symptoms of the two deceased, and recovered, it may justly be said that he took his daily quota of stronger spir-

its, which fact, we may justly assume, played the partial part of an antitoxin in preserving his health.

The deceased patients, A and B, had identical prodromal symptoms with the one I have just described, other than that the comatose and unconscious condition was continued and interrupted by convulsions and finally death. The report on record at the Milwaukee City Coroner's office, as regards the pathologic findings of the two who died, shows that all organs were normal, with the exception of slight pleuritic adhesions, and heart slightly hypertrophied with thickened valves in one; in the other case all organs were normal, with the exception of the kidneys, which were possibly congested. In both cases the heart ceased to beat in systole, and blood was fluid throughout the body, and was of a dark color.

That the two who died and the one in the case just cited suffered from one and the same disease, toxic hemoglobinuria, can not be questioned; thus, the only question of interest which remains, as regards cause, is: whence the source of intoxication? The three factors which might have produced the condition were: cold, carbon monoxide, or the impurities present in the wood alcohol which was used for cutting the shellac. A free discussion and investigation of these three cases is to be found in transactions of Wisconsin State Medical Society, 1898, and for reasons given there it is plainly evident that death was caused by the impurities present in the wood alcohol which was used for cutting the shellac. Can there be any doubt that these three patients had gone through recurrent attacks of toxic hemoglobinuria due to the inhalation of the wood alcohol vapors containing, "at times, aldehyde and acetone, the latter often reaching as high as 18 per cent. by weight; but aside from this there are cyanide compounds, notably methyl and ethyl cyanide which are highly toxic." The inhalation of an extraordinary amount of this toxic alcohol produced the climacterium.

Group 2 consists of patients E, F and G. Patient E is a good example of paroxysmal winter hemoglobinuria, and since I have treated patients through a number of attacks a description of an attack may be of interest.

Patient E was a strong man, 30 years of age, good family history, no specific or malarial taint, carpenter, and has been treated by me for eight or nine different attacks during the past five years. Those attacks are characterized by a decided chill, which comes on from five to twelve hours after an exposure to cold, after having been confined in the house for a few days. Chill is of a severe character lasting from one to one and one-half hours, and is accompanied by a temperature of 102 to 103, pain in back radiating to abdominal, inguinal and vesical regions, frequent micturition of dark brown urine, extreme frontal headache and general prostration. The temperature lasts from ten to twelve hours, beginning before the chill, and only abates after the chill and pains have subsided and body is bathed in profuse perspiration.

Urine contains hemoglobin and, in severe attacks, a few blood shades, but I have never found hemoglobin after twelve hours from the onset of the chill. He is able to attend to regular duties within one or two days after an attack, and the paroxysms are best treated when left entirely alone, aside from placing patient in a warm bed. Free use of warm-water bottles, and a liberal use of alcohol have been found to cut short the chill.

Upon one occasion before I had made a diagnosis. I resorted to the use of chloroform with the view of cutting short the chill, and it came very near costing the patient his life; the chill became the most severe one I ever experienced, lasting over three hours and terminating in convulsions and final recovery. It may be of interest to note that during the past year patient has become quite addicted to the use of alcohol, and during the past winter has been free from attacks, which, during the previous ten or twelve years, has never occurred.

Patient F (female) is of little interest other than that the hemoglobin was found in the urine until eight days after a severe burn involving the anterior and lateral aspects of left leg above and below the knee.

Hemoglobinemia.—In the last case the patient was a girl 7 years of age, good family history, has just recovered from a severe attack of acute meningitis, and on the seventh and ninth days temperature ranged from 103 to 104½. Blood was extracted according to Küssner's Method, by allowing several leeches to fill on the desired blood, and then the blood was allowed to stand in ice chest for twenty-four hours; the serum was of a ruby-red color and was centrifuged with negative results for corpuscles, but it gave the two absorption bands of hemoglobin, and disappeared upon the addition of ammonium sulphate; by a similar process, other than that the serum was filtered from the blood immediately after removal: the blood upon examination on the ninth day gave same results. The urine was examined on the sixth, eighth and ninth days, with negative results, thus proving that hemoglobinemia may exist without producing hemoglobinuria.

It is authentically stated that hemoglobinemia and hemoglobinuria are frequent complications in severe cases of typhoid, diphtheria and scarlet fever, and I am of the opinion that its presence should be noted as a grave complication and such medicines as favor its production should certainly be withheld, or used with caution. Potassium chlorate, antipyrin and all coal tar derivative febrifuges, etc.

Cause of chronic pyemia and pathologic condition of patient C before referred to: As to the cause of the many various symptoms, it can hardly be questioned but that the conditions were due to the increased disintegration of the red corpuscles of the blood, through the agency of the toxic wood alcohol substances before referred to, whereby an auto-intoxication of the tissues was produced, dependent upon the hemoglobinemia. Howell, "American Text-book of Physiology," says, on page 358: "Intravascular clotting more or less general in occurrence may be produced by injecting into the circulation such substances as leucocytes obtained by maceration of lymph glands, extracts of fibrin ferment, solutions of nucleo albumins of different kinds, etc." The Dorpater School teaches us that the hemoglobin taken up by the blood plasma in cases of hemoglobinemia of any consequence produces toxic action on the white corpuscles, leading to their disintegration and consequent formation of fibrin ferment. May we not also add a third class of corpuscles, the blood platelets, which are even more unstable.

From the foregoing it follows that a chronic auto-ferment intoxication was produced, and since the clotting of the blood is produced through the interaction

1 Perry L. Hobbs, Ph.D. Analytic and Consulting Chemist, Cleveland, Ohio.

of the fibrin ferment on fibrinogen, and (fibrinoplastin) there was unquestionably formed fluctulent fibrin coagulæ producing multiple emboli and hemorrhage of the small capillaries, thus producing the chronic pyæmia, temporary loss of vision, as also were the grave nervous symptoms produced in the same way.

Note on treatment of hemoglobinuria and hemoglobinemia of severe character.—In these cases, internal blood combustion being too rapid, a treatment with heavy oxidizing agents, such as ozone, peroxide of hydrogen and oxygen, would increase metabolism and disintegration of red blood-cells, thereby increasing the production of CO₂ and other effete poisonous products; it is therefore necessary to decrease this metabolism, which can best be done through the agency of reducing agents, the ones most available being calcium hydrate and nitro-glycerin. This also holds good in cases of gas poisoning (hemoglobinuria) which is mainly a CO poisoning. The giving of pure oxygen, ozone, etc., only does harm by adding more fuel to the flame, while the system has already been poisoned by the effete products of increased metabolism; likewise is the same true in our severe pneumonias, as in either of the two latter conditions.

SOME CONSIDERATIONS OF UREMIA AND ITS TREATMENT.

Presented to the Section on the Practice of Medicine at the Forty-ninth Annual Meeting of the American Medical Association held at Denver, Colo., June 7-10, 1898.

BY E. W. MITCHELL, M.D.

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS, MIAMI MEDICAL COLLEGE,
CINCINNATI, OHIO.

The numerous and varied symptoms which have been classed under the term uremia have always been an interesting theme for study and speculation. Of the many special theories which have, from time to time, been proposed to account for its phenomena, none have withstood the tests of investigation and criticism. The theory so long ago advanced that the *meteries morbi* is urea was quickly and generally accepted because of the ready proof that in these cases the urea was greatly reduced in the urine and largely increased in the blood and tissues. So firmly did this opinion become fixed in the professional mind that it yet largely prevails, although it has been repeatedly shown that, administered in much larger amounts than are ever found in uremic cases, it is harmless. The fact that experimental and clinical observation teach us that the decrease of urea in the urine gives us a fairly accurate indication as to the imminence of uremic attacks has helped to keep it associated in our minds as the important causal factor in spite of the evidence to the contrary.

The failure to inculcate any one of the chemic substances of the urine, or any one of the pathologic conditions as the essential causal factor, has driven us to the conclusion that many or all of them play some part. "The uremic poison is complex in character, and may vary, not only in the proportion of component elements, but also in the elements themselves," states about the conclusion to which we have come. Repeatedly it has been demonstrated that normal urine is toxic and that its toxicity is diminished in proportion as the kidney becomes impervious. The inference is the retention within the blood and tissues of these toxic materials which the urine has failed to carry away.

As to what these elements are and their properties, we have probably the most satisfactory answer in the investigations of Bouchard, as set forth in his most admirable monograph on "Auto-Intoxication." In the normal urine he has found seven toxic substances. Among these are two which produce convulsions: one inorganic, which he has proven to be potash; another organic, whose exact chemic nature is not established; one which produces coma: a fourth produces ptalism; a fifth is myotic; a sixth lowers temperature; one (urea) is diuretic. So accurate is the work of Bouchard and so closely do the physiologic actions of these substances correspond to the several prominent symptoms of uremia, that we are justified in assuming that we have in this state a toxemia, or to use the expression of Bouchard, an intoxication; furthermore, that the form which the intoxication will assume will depend upon the substance preponderating in the retained products. If it should be the convulsants, one or both, convulsions ensue; if the narcotic, we have coma. Mydriasis is often present. A lowered temperature is common. Ptalism is sometimes the most prominent symptom. I have seen one case in which it was the only symptom which excited suspicion of nephritis.

Mrs. F. H. came to my office complaining of excessive salivation. She had been under treatment by a physician for several weeks without any alleviation. She was three months pregnant; stated that the urine was free in quantity, although subsequent measurements showed it reduced; that she had been in good health, except for an illness a year previous, in which the urine had been very scant. Urinalysis showed a specific gravity of 1010, a small quantity of albumin and a variety of casts. Prompt treatment of the nephritis was followed by temporary improvement. A few weeks later an abortion occurred, anuria followed, with development of coma and death. Postmortem examination showed advanced diffuse nephritis.

Bouchard has shown that the narcotic substance in proper proportion has the power of neutralizing the convulsant. In this we may have an explanation of that anomalous fact that so often we have the most advanced impairment of the functions of the kidneys without the development of either convulsions or coma. Anuria not infrequently exists for many days without uremia. Reduced metabolism has never been a fully satisfactory explanation of this fact.

The recent importance attached to fermentative processes in the intestinal canal with the production and absorption of ptomaines has drawn attention to this as one source of intoxication. Bouchard has clearly shown how greatly the toxicity of the urine is increased by intestinal decomposition. It has also been shown that the physiologic secretions, such as the bile and saliva, contain toxic substances and their reabsorption may contribute to the poison. We have therefore four sources for the toxic materials: 1, the products of tissue disintegration; 2, food substances, especially the potash salts; 3, absorbable products of intestinal fermentation; 4, reabsorbed secretions, such as the bile and saliva.

I shall merely refer to another subject in this connection, but one not sufficiently worked out to be dwelt upon in this, which aims to be a brief and practical paper, namely: The functions of the liver in relation to the destruction of these poisonous products.

In view of our present knowledge of this work of the liver it can hardly be questioned that its failure

to properly dispose of the poisonous materials brought to it may be an important factor. Another point to which I shall merely allude, is that the quantity of albumin present is not a reliable measure of the danger of uremic accidents.

For the practical physician the chief value of chemic and physiologic revelations is the indications they give for treatment.

In the treatment of what may be called chronic uremic symptoms, such as headache, dyspnea, nausea, etc., we have involved the treatment of the chronic nephritis. The points I wish to insist upon in this connection are that metabolism shall be reduced by rest, intestinal fermentation guarded against by proper diet, catharsis, and if necessary the occasional use of non-absorbable intestinal antiseptics.

The bacteriologists have shown us that meat and meat products, such as soups and beef tea, are especially good media for bacterial growths, and that they produce the most virulent ptomaines. In meat also we have a source of potash salts; hence the importance of excluding it from the diet of all patients threatened with uremia. In serious cases, a strict milk diet; in the less serious, a milk diet with carbohydrate food is the most satisfactory.

Elimination by the skin is to be maintained, not by the use of drugs, but by baths, hot air, vapor or packs, selected according to the convenience and tolerance of the patient. It will frequently be found that one form is much better borne than another. Minute attention to all the habits of life, clothing, diet, the maintenance of elimination, will often defer for a long time the onset of uremic accidents. The prophylactic value of one drug is not sufficiently appreciated, namely, *veratrum viride*.

Several years ago an aged patient had several attacks of uremic coma; the pulse was hard and bounding, not only during the attacks, but also between them. Here was evidently an indication for lowering of the blood pressure, for which purpose we have no surer or safer drug than *veratrum*. In this case its administration in amounts sufficient to materially lower the blood pressure, held the attacks under control until treatment of the nephritis had restored him to health. I have since, a number of times, where uremia was threatened or feared with high blood tension, seen its good effects.

Notwithstanding most of our text-books warn against it, the use of drastic diuretics is too indiscriminate. In acute inflammations the great principle of rest is certainly as applicable for this organ as of others. It should not be stimulated to greater work, but should be as far as possible relieved by calling upon the complementary organs of elimination.

In the treatment of uremic convulsions and uremic coma there prevails a great diversity of practice and of opinion. During the convulsions, the first indication is to save life from the convulsion itself. The convulsion may be controlled by chloroform or by morphin, hypodermically. It is, however, bad practice to continue the administration of chloroform hour after hour, as is sometimes done, because of its destructive effects upon the blood corpuscles and because of its interference with oxidation. The difference in experience and of opinion with reference to the use of morphin is due to lack of discrimination in cases. For the immediate control of an acute attack, it is often most valuable, and usually safe. Its action in locking up secretions and diminishing elimination contraindicates its use in chronic conditions or its

repeated use in acute conditions. The great success of *veratrum viride* in puerperal convulsions has suggested that it may also be useful in the eclampsia of Bright's disease. I have twice used it with success in these cases. In a third case its use controlled temporarily the convulsion, but was followed by great reduction in the quantity of urine and finally coma and death. This, however, was a hopeless case; all other remedies had failed; the chief indication, the high tension of the pulse, was absent. *Veratrum* acts by lowering the arterial tension, by depressing the motor centers of the cord, and by promoting sweating.

Pilocarpin I mention only to condemn. Its sudorific effects are very often more than offset by the profuse salivary and bronchial secretions, and the patient is drowned in his own fluids. Having twice seen this result, I have abandoned it.

Bleeding, which for so long was abandoned, is again coming into favor. It will probably maintain a permanent place in the treatment of certain cases. At the present time it is especially used when combined with transfusion of normal salt solution. This leads us to the consideration of this newer means of treatment. Sufficient experience has now accumulated to prove its great value in the relief of uremic accidents. When the case is urgent, the saline solution should be given by transfusion into the vein in order to get its immediate effects. When the case admits of an hour or two delay, the solution should be given subcutaneously, since the former method is not without danger, and the latter is equally efficacious. If the blood pressure is low, the preliminary bleeding may be omitted. The reported cases, which are now numerous, show almost invariably prompt improvement. Ultimate recovery, however, depends upon the degree of disease in the kidneys. The immediate effect of the infusion is to dilute the poisonous matters in the blood and thus diminish their effects on the nerve centers. Elimination is enormously increased by the prompt production of profuse diuresis and diaphoresis. We have herein a means of tiding many patients over the emergency, giving them the opportunity to recover, provided the anatomic changes in the kidneys are not already too far advanced.

SOCIETY PROCEEDINGS.

The Medical Society of the State of New Jersey.

One Hundred and Thirty-second Anniversary at Asbury Park, June 28, 1898.

(Continued from page 185.)

SECOND DAY.

A paper was read by Dr. WILLIAM PIERSON, third vice-president, on

THE UMBILICAL CORD.

Up to the present day no settled plan of treatment of the cord has been agreed upon. Teachers differ widely, yet this is a subject demanding better consideration. He described the treatment it received in the inferior animals, torn by the struggles of the offspring or bitten off by the mother. The Indians do not sever it until the placenta is expelled. The Japanese tie close to the body and preserve the cord with the family archives until the child arrives at maturity, when he constantly carries it about with him and it is finally buried with him. Non-ligation will do when the cord is crushed, torn, chewed, etc., so that bleeding is not likely to occur. The ligature is safer, as cases have occurred where hemorrhage has come on, with fatal results, even when care had been taken. Usually it is tied as soon as the child cries; this may be well, but be not

too precipitate as we may thus rob the child of needed blood. As no harm is seen from late tying, let the child cry and breathe well for a few minutes, or wait till pulsation ceases. Narrow linen bobbin, sterilized, is best for the ligature. Silk is apt to cut the vessels and cause hemorrhage, catgut is unsuitable as it rots rapidly. The usual length from the body is about two inches. The long stump is urged, to avoid tying the intestines and to leave room for a second tie should hemorrhage occur. The short stump leaves less dead tissue, less fetor; it shrinks and sinks into the depression becoming a scab or crust less liable to be pulled or torn, hence it is better. The dressing is to aid the separation, cause complete cicatrization, lessen risk of sepsis. We must encourage the drying, hence not use grease or wet bandages. Absorbent cotton is now in general use; it prevents contact with the skin and does not prevent rapid drying. Free exposure to the air is well and the application of absorbent antiseptic powder prevents excoriations of the skin, as boric acid powder, or rub the end with a moistened bichlorid tablet; dress daily. He has followed, for the last fifteen years, the plan of stripping the stump so as to get rid of all blood and gelatinous matter, leaving it nearly dry; then it may be left without any dressing and falls off like ripe fruit. Under the moist plan the stump decomposes and sloughs off; this may extend to the umbilicus and an open ulcer follow, with great danger to the child. He has seen several such cases and several died, and it was no doubt due to infection by the umbilical vessels. Next as to the belly-band. Thanks to the efforts of several teachers, the importance of this has been proved a fallacy. The reasons urged for its use were warmth, and to retain the cord dressing. Neither of these is necessary, and to retain the cord dressing a heavy netted band may be used. If no dressing is employed then the net is not needed. The belief that support of the abdominal walls is necessary is also a fallacy. Again it was thought to prevent the occurrence of umbilical hernia. This, too, is not true. The band may prevent an expansion of the walls, compress the contents, and thus produce what we wish to avoid. Many believe they have seen this as a result of tight bandaging. The bandage then should be abandoned. The anomalies, accidents and diseases of the cord deserve more attention. Death of the fetus in the womb is not often determined as to its cause. Still-birth is given as the cause of death, when the cause of the still-birth should be given: 90 per cent., he believed, was induced by trouble with the cord.

In all cases care should be taken to determine the exact condition of the cord so as to be able to say if any anomaly here caused the death. The length of the cord varies from no cord to five feet; usually it is two and a half feet long. The implantation of the cord into the placenta varies; marginal, velamentous where the vessels pass for some distance between the corion and amnion, before entering the placental structure, or the cord may be received in the fold of the amnion. The latter is dangerous to the fetus as the vessels are liable to traumatism and rupture, causing death from shock, asphyxiation or hemorrhage before delivery. Again the jelly of Wharton may be less or greatly increased in quantity; the only danger is from an excess causing the slipping of the ligature and, as it shrinks, hemorrhage. Here, where very excessive, do not tie till the size is reduced by stripping. Torsion, knotting and coiling of the cord are often observed; the latter may produce occlusion of the circulation and death. This occurs most where the cord is very long. Knots are rarely tight, still such may occur. Coiling round a portion of the fetus is of immense importance. It shortens the cord, may produce strangulation of the fetus, may obstruct labor and may cause detachment of the placenta. All these accidents are really beyond the reach of aid, but in delivery, when a part is encircled, draw down the cord, doubly ligate and sever, after which deliver as speedily as possible, to prevent dystocia and death of the fetus. Pro-lapsus of the cord is important, causing death in very many cases. It is not a very common accident. Here, place it beyond the point of compression by the parts of the child, and accomplish delivery as rapidly as may be commensurate with safety of the mother. The postural position is best to permit the cord falling back to a safer position, but occasionally fatigue to the mother is so great that this must be abandoned. The gum catheter and loop may be employed to replace it and often succeeds, but the manual method is best when possible, but with all care is needed when the membranes are not ruptured to prevent this, as it adds to the trouble. Podalic version gives much better results when the circulation is feeble or has stopped, then delivery of the head with the forceps will give the best results.

Dr. J. C. McCoy related the conditions in a case of foreign body in the esophagus, where the child had drawn in a small tin whistle; he failed to extract it with the long forceps, dys-

pnea at first was very great, then the wire was tried. For some reason the trouble appeared much lessened, hence the parents were unwilling to have any operation performed. In the night the dyspnea returned, the child was brought to the hospital, operation performed, and after sixteen days from the removal of the body, the child was well. He condemned the efforts to extract by an instrument as often highly injurious.

Dr. W. B. JOYNSON reported a case of foreign body in the bronchus and the operation of tracheotomy.

MILK AS A CULTURE MEDIUM AND ITS CAPACITY TO SPREAD INFECTIOUS DISEASES

was discussed by Dr. R. C. NEWTON. Recently there has not been a material addition to our knowledge of bacteriology, perhaps because the subject is so difficult. Keer has followed Schwartz in advocating milk of goats in place of that of cows for invalids and delicate children. It is more uniform in quality, the animal selects her food more carefully and avoids much fluid. The animal is immune to tuberculosis, hence its milk does not need boiling. It has been demonstrated in fresh milk that the fat globules are immediately taken up into the blood and build up the cellular tissue. This constituent of cow's milk is destroyed by boiling. Boiling also alters the fluid albuminoid of the milk that it is difficult to dissolve and assimilate it in the alimentary canal. Milk should not be boiled when its nutritive value is required. All writers agree as to the great value of milk as a food. Skim-milk fed to animals gives good results except in lambs, which do not seem to assimilate it. Working horses have been so fed with excellent results. A seemingly unnatural food for milch cows is skim milk, but it has been satisfactorily practiced. The milk is heated to 155 or 160 degrees and rennet is added; while it is thickening, an equal weight of chaff or finely cut straw is mixed in, well stirred; then it stands two hours and the whole mass is left to ferment for forty-eight hours. Thus prepared, it is claimed that a gallon of skim-milk amply replaces four pounds of concentrated grain food. Feeding milk to hogs has been found to cause them to grow, digest well, and produce more uniformly high grade pork. Another writer insists that sweet milk makes the right kind of pork and sour milk is not good for them. The use of milk as an economic food is gradually increasing. Boat crews trained on milk can always outrow those trained on beer; no doubt this applies to race horses, etc. Hygiene of the stable should now be attended to. Study the manners and customs of the cow in her wild state and learn how health may be preserved. Do not keep too large herds under one roof. A number of writers have indorsed the views he offered last year and insist that milk should be fed to children as soon as possible after milking. The milk laboratories are having a struggle to exist, and it is doubtful if they can be kept open. Pasteurization of milk has encountered much opposition. Koplik of New York speaks in no uncertain terms. Most of the germs in milk which are harmful to children are not affected by pasteurization. Gastro-intestinal disturbance follows. Milk poisoning has been seen after administration of pasteurized milk. As to the spread of infectious disease by milk, there are many cases to report. In Philadelphia an epidemic of diphtheria followed the milk route of a man; the dairy was in an unhygienic condition and the sale of the milk was suspended. There were eighty-six cases and twenty-two deaths. Vaccinia in Caldwell appeared and spread rapidly and caused great inconvenience to the dairymen. The cows were isolated and the sale of the milk suspended. The veterinarians who examined the cows claimed that a majority of the lesions were due to what they called "feed boils," little abscesses on the teats and the udders when the cows went out to grass after being kept on grain and dry food during the winter. These boils need investigation, as many do not understand their etiology, etc., and some deny their existence. There is no doubt such a condition in milch cows more or less constantly in the spring.

Experiments to show the effect of infectious germs on the milk glands showed injected cultures of anthrax killed the animals but did not infect the milk. By the injection of pus cultures into the veins, in five to eight hours they were present in the milk. In two women suffering with puerperal septic infection, streptococci were found in the blood but not in the milk. They conclude that infectious germs gain access to the milk by circulating through the glands in the blood stream, and to enter the milk they must pass through the glandular substance through some injury. It is recommended that regular microscopic examinations of milk to detect pus must be made. Milk is to be rejected when over an average of five pus cells are found on the field of a twelfth-inch oil-immersion lens. An extensive epidemic of typhoid fever was traced to a dairy near Paterson. In the study of tuberculosis in milk some advance has been made. Tubercle bacilli do not always develop in

milk but remain alive and virulent for at least two months and a half. One believes it due to overmilking, and urges the law to compel cows to go dry three months after gestation. Authorities differ as to bacilli in butter. One observer examined eighty specimens and did not discover it in a single one. One believes that all tuberculosis in the human race comes from the dairy. Mr. Nathan Straus of New York has no doubt saved thousands of infants' lives by supplying sterilized milk at cheap rates. It is getting to be a fashion to work and write and spend money for the sake of obtaining wholesome germ-free milk. Even of a Tammany brave it is reported, after being appointed a sanitary inspector in New York City, that he expected to make \$20,000 by admitting rotten meat, vegetables and fish into the city, but he was going to get up "a b-l of a reputation" by shutting out impure milk. Eternal vigilance is the price of wholesome food products of all sorts. Deaths among children are due to lack of food inspection and food laws; even as high as 35 per cent. Artificially fed children can never be safe from the great white death. Let us never relax our efforts till proper and sufficient dairy laws are enacted and enforced. I have in my investigations discovered a custom so mean, revolting and so devilish that I must speak of it. The sale of bodies of dairy animals which have died of disease or accident to the bologna sausage man. This obtains even in the better class of dairies and would suggest that the dealer in "bob veal" is a philanthropist in comparison with the bologna sausage man. I would urge a law that all milk vendors shall be obliged to take out a license as to the condition of their herds, sworn to, water-supply, feeding, housing, caring for stock, milk handling—the license to be revoked when these matters fall below the standard, or when he shall fail to give notice of sickness among his cattle, his family or employees; the testing of all milch cattle with tuberculin to be compulsory; the selling of cattle which die of disease or accident, etc., to a bologna sausage man to be punishable with fine and imprisonment.

D. J. LEAL continued the discussion, considering

MILK AS A CARRIER OF INFECTION.

He said: Time will not allow me to make more than a brief statement of present opinion on the subject. That opinion may be summed up in the following propositions: 1. That milk is a carrier of infection, more so than any other one article of food. The theoretic and scientific basis of this proposition is explained by the discussion on "Milk as a Bacterial Culture-Medium"; its truth is established by a vast mass of evidence which has been accumulated by practical experience. 2. That the diseases, the infection of which is certainly carried by milk, are typhoid fever, cholera, tuberculosis, diphtheria and scarlet fever. This statement, in so far as it relates to scarlet fever, is based upon analogy and practical experience. Milk is also capable of developing and maintaining the vitality and the virulence of certain groups of bacteria, the presence of which give rise to intestinal irritation. Besides, though not proven, it is considered scientifically possible, and practically probable, that the infection of smallpox, typhus fever, tetanus and malaria may be conveyed through this means.

Now as to the common methods of infection of milk by typhoid fever, cholera, tuberculosis, diphtheria and scarlet fever. By diphtheria and scarlet fever it is: 1. Through exposure to infected air. This air may have become infected through some patient suffering with one of these diseases, or indirectly through some person or thing thus infected. 2. Through exposure to infection in the handling, directly or indirectly; directly, through handling by some person or persons suffering with these diseases at the time; indirectly, through some person or persons, dishes, containers, apparatus or utensils which have become infected by such person or persons. By tuberculosis it is: 1. Through exposure to infected air, this air containing dust formed in part of dried tubercular sputum. 2. Through direct infection from some person or persons suffering with the disease, as by particles of expectoration flying into exposed milk during an attack of coughing, by handling with infected hands, etc. 3. Through some person or persons, dishes, containers, apparatus or utensils infected directly by some person or persons suffering with the disease, or indirectly by infected dust, etc. 4. Through cows having tuberculosis udders. By typhoid fever and cholera it is: 1. Through the intentional or accidental addition of infected water. 2. Through handling with hands infected by discharges or water. 3. Through dishes, containers, apparatus or utensils infected in handling or by water. 4. In the case of typhoid fever infection through infected ice.

It follows from the above that certain rules must be carefully observed in order to prevent milk from acting as a carrier of infection. 1. That milk for food purposes must be taken only from healthy animals. 2. Every precaution must be

taken to prevent exposure to air which by any possibility could be infected. 3. Those handling the milk must not only be personally free from these diseases, but must also be protected from infection through others. 4. All premises, dishes, containers, apparatus and utensils must be guarded from infection through persons, air and dust. 5. All water and ice used in connection with milk must be free from infection. That these rules should be properly carried out is of vital importance to the consumer and of much interest to the profession, the function of which is not only to cure disease but also to prevent it. Unfortunately, however, the producer does not always look at the matter from our standpoint, and is apt to resent, as interference with personal and property rights, our well-meant efforts in this direction. The only solution of the difficulty is the wider dissemination of knowledge upon the subject, and therefore the better education of the people, which must come through the medical profession.

First practical illustration.—In October, 1889, thirty-four cases of typhoid fever were reported to the Board of Health of Paterson. Investigation showed that twenty-seven of these cases were supplied with milk from the same dairy. Further investigation by my friend, Dr. William K. Newton, then State Dairy Commissioner, and myself, disclosed the following facts: Said dairy was situated in an out-lying township. The water-supply was from a spring in the milk house, which was about two hundred yards distant from the other farm buildings and out of the direct line of drainage, and from a well in the barn yard. The well was so situated as to receive the general barn drainage, as well as that of an immense pile of manure placed within fifteen feet of it and in the direct drainage line. Chemic examination of the water-supply showed the water of the spring to be pure and that of the well to be badly contaminated. The dairy people declared that neither the milk, the cans, the dishes nor the utensils came in contact in any way with the water of the well, that the cover full of water which they admitted putting in each can of milk "for the purpose of preserving it," came from the spring, and that cans, etc., were washed with the same water. They denied ever having anything connected with the milk business anywhere about the place except at the milk house, and asserted that water from the well was only used for drinking purposes by the men employed about the barn, and for washing purposes about the house. We also found that on the 14th of the preceding month a stranger from Pennsylvania had been employed about the place. He had complained from the first of not feeling well, suffered from fever, diarrhea, headache, prostration, etc. He held out until the 25th when he was forced to return home. On October 5 another man who had been employed upon the place steadily for two years became ill about the same way and left on the 12th to enter the hospital. Our twenty-seven cases in the city using this milk all developed between October 2 and 24. We succeeded in locating the two employees, one in the Bethlehem, Pa., hospital, the other in the Paterson General Hospital, both suffering with typhoid fever. We also found that both these men while ill on the place had been in the habit of using the manure pile which drained into the well as a convenience. It was easy for us to reach the conclusion that the first man had been a "walking case" of typhoid, that through his use of the manure pile he had infected the well, and that the second man had become infected through drinking the water of said well. The difficulty was to connect the infection with the milk, as according to all the evidence obtainable neither man had anything whatever to do with the milk business. The missing link was found, however, when a female servant confessed that she had been in the habit of washing the can covers with water from the well. The well was filled up on the 16th and no cases developed after the 24th.

Second practical illustration.—The average number of cases of typhoid fever in Paterson during the months of November and December for the six years preceding that of 1896 when we were in the midst of a general epidemic due to an infected public water-supply was, during November 8 cases, and during December, 5 cases. During the first half of November, 1897, 3 cases of typhoid were reported to the Board of Health. From November 15 to Jan. 1, 1898, 142 cases were reported. All of these 142 cases became ill between November 5 and December 15. All but 5 became ill between November 14 and December 15. The number of these cases in well-to-do families was far out of proportion, considering the character of our population. Ninety-nine of them received their milk supply from a certain creamery for all or a portion of the fifteen days preceding the commencement of their illness. Of the 43 cases left, 14 had used cream, or ice-cream, or soda water containing cream from the same creamery, on one or more occasions, between the fifteenth and fifth days preceding their illness. Thus of the 142 cases developing between November 5 and December 15,

only 29 could not be connected with the product of said creamery. The natural conclusion to those who have had experience in tracing epidemics due to milk, and understand its difficulties, is that at least a portion of these 29 cases could have been connected if it had been possible to have obtained the facts in every case. Among the handlers of the milk in town or among their families, were 8 cases of the fever. In the Paterson Orphan Asylum, which was the only institution supplied with milk from said creamery, there were 9 cases among the 70 odd inmates. On November 29, I became convinced that everything pointed to the milk as the source of infection, and therefore telegraphed to Dr. Henry Mitchell, Secretary of the State Board of Health, requesting that he have an investigation made of the state of affairs at the suspected creamery. Such investigation was made by Dr. A. C. Hunt, State Inspector, on December 1. During the evening of the same day he reported to me a very suspicious condition of affairs existing there. He had been unable to find any possible source of infection outside of the creamery. At the creamery he had found that water from a brook was pumped into the creamery for general use through a pipe, the intake end of which was from 115 to 139 feet below the privy belonging to the proprietor's residence, which privy overhung said brook. Four or five other privies were situated upon the banks of the same brook within an eighth of a mile. He was also informed that the three sons of the proprietor were ill in the house with remittent fever. He at once ordered the pipe taken out. At Dr. Hunt's request I accompanied him on December 2 for the purpose of making a more thorough inspection. I found the creamery situated upon the bank of a brook. The premises consisted of the creamery, stable, ice-house, cheese house and residence. The privy overhung the brook about 100 feet above the creamery, and was directly in the rear of the cheese house and residence. The water-supply to the creamery was first from the brook through a pipe as described above, which pipe had been removed before my arrival, according to orders given the day before by Dr. Hunt, and second from a spring in the cellar of the cheese house through another pipe. The water-supply of the cheese house was from the spring in the cellar, and the residence was supplied from the same source through a pipe by means of a pump. The house drain, a wooden box, passed through swampy and made ground at a higher level and about fifteen feet above the spring, entering the brook a few feet above the privy. We found that the creamery received the milk of fifty-three dairies, and that said milk was all handled at the creamery and sent to Dover, Morristown, Paterson, Newark, Arlington, Jersey City and New York. Inquiry from physicians, the creamery proprietor and other residents, failed to give any clue to suspicious illness at any of these dairies. I will here state on the authority of the State Dairy Commissioner that all of these dairies were afterward inspected and no source of infection found. The three sons of the creamery proprietor were visited, examined and found to be suffering with typhoid fever. In this diagnosis both Dr. Hunt and the attending physician concurred. Their temperatures varied from 102 to 105 degrees; the typic tongue, eruption and diarrhea were present; they suffered from nose bleed and presented the abdominal symptoms. Not a single important symptom of typhoid was absent except intestinal hemorrhage, and I am informed by Dr. Hunt that two of them afterward suffered from that condition. Dr. Richard N. Connolly of Newark, also produced the Widal reaction in specimens of blood taken from these patients, and isolated the bacillus of Eberth in a specimen of water taken from the cooling vats in the creamery. Taken all in all, considering the arrangement of the premises, the privy, the house drain, the water-supply, the milk handled upon the premises, the presence of the three cases of typhoid, a better illustration for a lecture upon "How our milk supply might become infected by typhoid" I can hardly conceive. There followed a history of the three cases in detail.

I have already stated that milk from this creamery was shipped to Dover, Morristown, Newark, Arlington, Jersey City and New York, as well as to Paterson. I have no information from Dover or Morristown, but am informed by health officials of the other cities as follows: Newark, unknown number of cases among those using milk from said creamery. Arlington, 17 cases and 6 suspected cases, became ill about November 20; all except one used milk from said creamery. Jersey City, 35 cases taken ill November 15 to 20; 24 used milk from said creamery. New York, 9 cases found among those who had used said milk.

Third practical illustration.—A small outbreak in connection with this greater one may possess some interest. A farmer in an adjoining township ran a milk route in Paterson. His supply was from his own cattle. Running short on November 13, 19 and 27 he supplemented his supply with milk from the

before mentioned creamery. Between December 1 and 10 his son, living with him, and five of the patrons of his milk route in Paterson developed typhoid fever.

Fourth practical illustration. On Jan. 1, 1898, a milkman, living and doing business in Paterson, became ill. He was supposed to have malarial fever. On January 9 Dr. John C. McCoy was called in and found him suffering with typhoid fever. In the interval between the first and 9th he had continued at his business, personally engaged in bottling and otherwise handling his milk. Dr. McCoy, at his visit on the 9th, at once ordered the patient to bed and thus broke up his connection with the business. Between January 15 and February 1, 27 cases of typhoid fever developed in town; 19 of these cases were supplied with milk by this milkman during that period of his illness between January 1 and 9. The outbreak ceased suddenly here, only four scattering cases developing during the whole month of February, and these having no connection with said milk. One of this series of cases was especially interesting. I personally attended the case and established the facts beyond the shadow of a doubt, the patient himself being a physician and his attendants more than usually intelligent. On the morning of January 2 the Doctor's usual milk supply failing him, the deficiency was supplied from the establishment of said milkman. It was the first and only time that his milk had been obtained at that place. The doctor used said milk upon his oatmeal and drank two glasses of it. On January 15 he became ill with what proved in a few days to be typhoid fever.

There is no other one article of our food supply which is more valuable, which is more capable of harm, and which requires more watchful and constant care. Ignorance and selfishness should not be allowed to stand in the way of our exercise of the right of self-protection. Thousands of lives are lost every year through want of that constant and watchful care. The general public is dependent for its safety in this respect upon the medical profession. That responsibility must be met. We, as an organized profession, should insist that the State throw around this product of such vital importance, every protection which science and experience teach to be effective.

On Wednesday afternoon, Dr. JUDSON DALAND read a paper on

THE METHOD OF ADMINISTERING AND THE USE OF ENTEROCLYSMS.

The only instrumental help is a soft rubber tube, a fountain syringe and a funnel. We must not use anything which will irritate the internal mucous membrane. He preferred a rectal tube with rather thick walls, two feet long and three-eighths of an inch in diameter. Its surface must be as smooth as the finest bougie, the tip slightly tapering, rounded and with a direct opening. Eight inches from the end is a black line encircling the tube. The patient assumes the position and when the lower bowel is emptied by a small enema the soft tube is well oiled and slowly introduced by rotary movement till it passes the sigmoid flexure and enters the colon. The right lateral position is assumed when the cecum and ascending colon are to be irrigated. In an adult, eight inches of the tube must be introduced before entering the colon, as indicated by the black line. Occasionally the tube doubles on itself or is caught by folds of the mucous membrane. This can be overcome by allowing the water to flow from the syringe while being introduced, thus dilating the bowel and smoothing the mucous membrane before it. If much difficulty be found, or pain, it may be from impacted feces, hemorrhoids, tumors of the sigmoid flexure or rectum, etc. Skilful manipulation generally is successful, or we may use the knee-chest position. The raising or lowering of the reservoir will increase or diminish the flow. The liquids employed are water, salt solution, sea water, boric acid, nitrate of silver solution, etc., the temperature between 40 and 105 degrees. The quantity depends upon the age and sex and object desired. A child takes one pint, an adult, two, three or four pints. Ten minutes should be occupied in the work and the liquid be retained that long before being evacuated. An urgent desire is felt at first, but can be overcome by pressure on the anal or peritoneal region and rest in bed. When colicky pains due to gas from too rapid introduction occur, let off the liquid or introduce it slower. If there is abdominal relaxation, bandage beforehand. Use it daily every four hours, or alternate days, according to circumstances. Even if the first effort is not successful, we often succeed by a renewal. It is employed in severe cases of cholera, tannic acid being the medicine used, which was vomited, showing that it had passed the valve. The conditions in which the enteroclysms are indicated, are obstinate constipation, autointoxication, gout, chlorosis, pernicious anemia, conditions indicating an increased supply of water, as a diuretic, diabetic coma,

uremia, cholera Asiatica, typhoid fever, cholera morbus, summer diarrhea, enteritis, pseudomembraneous colitis, chronic dysentery, sunstroke, hyperemia, volvulus, invagination.

In the discussion of Dr. Daland's paper, Dr. NEWTON alluded to the use of chlorin water, and the good results of cold water, and in cholera infantum the temperature is readily reduced by the continual use of water per rectum.

Dr. BENJAMIN regarded this method as valuable in typhoid fever. When he found a sudden fall of temperature he generally saw a hemorrhage from the bowel. Then this plan was good. Ice cold water was sure to arrest the hemorrhage. It also proved very useful to produce antiseptics.

Dr. BARKER had for years employed this means, especially in catarrhal jaundice. He employed ice water followed by hot water later in the day. It is sure to bring away the obstruction. He differed as to the length of the tube. It must be long enough to carry well up into the bowel, as the solution is better retained.

Dr. DALAND, in closing, had not mentioned antiseptics, as the washing out makes this less needed and he feared danger from the absorption of the article used. Chlorin was useful, as was a 3 percent. solution of tannic acid. It inhibited the growth of bacilli; in cholera infantum it was of great value; practically the saturated solution of boric acid is the antiseptic.

Dr. W. B. JOHNSON read an essay on

SCHOOL HYGIENE, WITH REFERENCE TO THE PRODUCTION OF OCULAR DISEASE.

He alluded to the consideration of this subject as early as 1800. The special point in this country is the construction of school buildings; arrangement of rooms, furnishing and lighting, as related to ocular disease, was brought forward by Dr. P. A. Callan of New York. He had concluded after many examinations of school children that the methods of construction were a means of injury to normal vision, as also to the general health and physical development. Improvements in some locations have taken place. The expense is the main cause of the building of schools without the proper arrangements. The movement in behalf of better construction is gaining strength. Scientific facts are not appreciated by the layman. We must get the public to know the great needs of our children in the schools. The most important adjunct is the expensive ventilation. The subject is not studied sufficiently so as to operate the less expensive methods. The window should be used for ventilation and aeration in the absence of the students. The authorities of our State should have regular systematic ocular and physical examinations of our school children. Other States have made vast strides in this direction.

The report by Dr. G. T. WELCH, Chairman of the Sanitary Committee of the Board of Education, shows a preponderance of eye disease, etc., in schools poorly lighted and ventilated over those recently erected, with more direct light, etc. This caused a bill to be presented prohibiting the erection of schools where it is possible for them to be overshadowed by other buildings. It failed to pass and there is now a retrograde action perceptible. Other cities have taken up the matter, and in Paterson a committee has been appointed to confer with the Board of Education to endeavor to have such improvements obtained. Philadelphia and a number of Western cities are working up the matter. New York has instituted the examination of children in public schools with a plan so simple that results are easily obtained. He gave in detail the schedule for the teachers. He alluded to the inspections as practiced in Boston, Chicago, etc., and the valuable results obtained both as to eye troubles and contagious diseases. This will result in placing children with physical defects in separate classes with selected studies such as they will be able to perform, and thus not detract from the proper advancement of those able to do the entire work of the curriculum. We thus may avoid the constant falling by the wayside of so many who are physically unable to perform the work of the usual curriculum. Scientific observers show that the myopic state is the result of ocular application. This is constantly increasing and the time has come when we must prevent its further increase. Recent examinations of volunteers show a very high percentage of rejections, especially of city-bred men. This should impress our citizens of the necessity of action; public institutions must learn that the work intrusted to them must be in accordance with the best known methods. The ideal school house must be built upon a site selected with a view to the possibility of providing adequate light supply for every classroom. This should be direct, not transmitted. The window space must be arranged in relation to the desks, that all light enter from the left and behind the scholars. He then gave details as to scientific construction of the windows, etc., maps,

blackboards, etc., to be so placed as not to reflect the light and visible from every part of the room, with a dull surface; the walls etc. to be tinted in light colors, preferably subdued grays or buffs, dead finish, the ceiling lighter than the walls. Ventilation can not be overestimated; the air must be entirely changed once every twenty minutes. The furniture should be of stable character, size proportionate to the pupil who is to occupy it. Desks must be adjustable. Improperly adjusted seats and desks produce many forms of spinal troubles. Specializing the work of teachers requires the changing from room to room of the pupils, making it impossible to occupy the appropriate seats by those who have had them adjusted for them. Teachers might better be moved, but they object, as interfering with the preparation of blackboards, etc. Still, some plan might be obtained to obviate the physical injury to the pupils, even though attended by difficulties to the teachers. Paper and black ink must be used rather than slates or lead pencils. There should be roomy, airy, well ventilated cloak-rooms, the toilet arrangements of the most approved style, and constantly guarded lest they are fouled. Any child applying for admission, having reddened or weak eyes, should be at once referred for an examination as to the question of the communicability of its condition, or any developing such condition should be at once sent home with a note and be obliged to present a certificate citing the harmless character of the disease. Physical as well as ocular disease results from faulty light, improper position at work and bad air. Inspection then is demanded daily. Lectures at intervals on subjects pertaining to school hygiene, etc., will be of great value both to teachers and pupils. While it is likely that many will still suffer from the defects of schoolhouses and the want of proper arrangements, yet the belief is that progress now once started will be constant and more rapid, till in the near future we shall see each and every school fully up to the mark, and in every way provided for the physical welfare of all.

Dr. L. F. BISHOP of New York read an essay on

THE CARE OF CHRONIC CARDIAC DISEASE, WITH A CONSIDERATION OF RESULTS.

In the mitral group are included most young people who have acquired a cardiac lesion as a complication of an acute infectious disease, who, while preserving the appearance of good health, still are subject to passive congestion, the so-called cardiac cachexia. This gives them the high color so becoming but so significant of venous stasis. These are less prone to an increase of the cardiac lesion. The aortic type includes, generally, older people, or at least young people who age prematurely, are apt to become anemic, emaciate, develop chronic nephritis, etc. Many will have lesions of both orifices, but will classify themselves under one or the other of these types. There is probably an underlying condition. In a person without a tendency to arterial disease the mitral valve is the more liable to suffer in an acute attack, while where there is a tendency to endocarditis the aortic valve, situated where it is, practically at the beginning of the largest artery, is the seat of inflammation. In the management of chronic heart cases, it is well to bear in mind these two types, because what may benefit one may be prejudicial to the other. The difference is almost the difference between rheumatism and gout; rheumatism representing the mitral cases and gout the aortic cases. It is not necessary to distinguish particularly, from the view of therapeutics, between mitral stenosis and regurgitation. Congestion of the liver undoubtedly has a broader influence upon the whole economy than we are prone to believe, the blood circulated through the liver again and again without being supplied with those elements that favor its healthy metabolism and which seem essential to its proper purification. In addition, the liver has the direct function of producing bile, the natural primitive laxative. The organ is found enlarged and sometimes its functions are interfered with so as to cause complete jaundice. The functions of the liver must be stimulated from time to time by appropriate means, but local applications as to the chest should not be neglected. Congestion of the kidneys is benefited by digitalis, on the circulation, but where there is albuminuria it must be treated as nephritis. Causes of local congestion, whether from displaced or inflamed organs or overloaded viscera, must be treated. Chronic constipation is a foe to these patients; it must be met with diet, training and drugs. It is a vice of indolence; will-power must be induced. Give the fluid extract of cascara in a single large dose at bedtime, instructing the patient to modify the dose nightly, as it secures a free evacuation. At the end of a month the dose may be reduced by drops each night till reduced to five drops. This is continued for its moral effect, to be gradually abandoned. Intermitting catharsis almost always fails. When laxatives must be used, the patient is instructed to

repeat the same process, not to take a single large dose to be followed by diarrhea, but take the drug for a series of days, gradually abandoning it. The evils of constipation are so great that this introduction of the subject is fully justified. The idea of influencing the course of cardiac disease by physical means is no new thing, and yet there is hardly any therapeutic system with so radical a basis that has been as frequently advocated and then discarded or neglected. The reason is not clear, but may be traced to the injudicious claims of over-enthusiastic advocates. The advocates of the Schott system bring forward evidence to prove that there is great improvement under exercise slowly and regularly carried on. The chief effects claimed are a slowing of the pulse and a diminution in the size of the heart. The plan of treatment is not recommended in aneurysm or where there is a high degree of tension, nor is the exercise all of the treatment. The patients also receive baths with mineral constituents, as chlorides of sodium and calcium, at first at a temperature of 92 degrees from six to eight minutes, then the proportion of sodium is lowered and free carbonic acid gas is present in abundant quantities. Climate, with special reference to altitude on cardiac cases, must be studied as to the individual. When the valvular lesion is grave, the patient should remain at a low level. But in cases where the circulation is well carried on, but with persistent murmurs, with the probability that anemia is a strong factor in their production, patients may improve in a high sunny climate. It seems to be agreed that the removal to a high altitude has the immediate effect of increasing the red blood corpuscles. The cause is not well established. I would suggest that the rarefied air brings an amount of oxygen to the lungs in a diminished quantity, thus creating a demand for more corpuscles to gather in the oxygen for the use of the system. Change from an indoor to an outdoor climate is a great deal a matter of volition. The open windows at night and the waking hours spent out of doors, with the adaptation of home life to the system that would be found in places specially resorted to for health, approximate closely in results what is accomplished by health resorts. Too often the means for a change of climate are said to be lacking when the knowledge and moral force are really the elements needed. The influence of the mental health upon the course of cardiac disease is well shown by instances of persons who go on in comparative comfort for many years through the cultivation of even living and quiet thinking. This is especially true of the heart damaged in early life that has placed a limit on the possible activities. These patients who adapt themselves to the inevitable are not made unhappy thereby, but are often rather spared the irritation of the average man who believes that his progress is retarded by his own indolence. In fact, the treatment of heart disease is the treatment of the whole body in each of its divisions. The physician must stand in relation to the patient with chronic heart disease as the captain does to the ship, constantly guiding, and not as the occasional pilot taken aboard when special danger threatens. The physician has the power to save the patient from dangerous conditions, but at each time with a loss of reserve force and with a prospect of a sooner return to the same dangerous condition. Far better is it for the physician to be put in charge before the rocks are encountered and disaster is threatened. It is important to dispel from the mind of the cardiac patient the notion that his chief danger of death is a sudden one. He should be instructed that the probabilities are that if he dies of his heart trouble the death will be gradual, and he should be warned that the first part of the descent from the plane of good general condition marks the danger point. He must be taught to believe that in him disturbances of digestion, loss of color, malnutrition, particularly dyspnea and edema of any kind, should immediately result in an overhauling of his plan of life and system of management.

(To be continued.)

PRACTICAL NOTES.

The Efficacy of Urotropin in Phosphaturia is announced by L. Casper of Berlin, who states that one to two grams a day will suppress the phosphaturia, which does not reappear again for a long while, if at all. The use of mineral acids, the usual treatment, is only effective while the medication is kept up.—*Semaine Méd.*, November 10.

Hemoptysis.—In the *Philadelphia Medical Journal* for July 16, Thomae makes a report on the use of atropin hypodermically in the treatment of hemoptysis. In his seven cases the drug acted promptly and well, except in one case, and often

when all other remedies had failed. He believes the evidence sufficient to justify the continued use of atropin hypodermically in any serious condition. He considers the ice-bag to the chest of doubtful utility, except that it quiets the mental state.

Restoration of the Urethra.—Froelich reports two cases in which the urethra had been destroyed in the course of childbirth, in which he has restored the canal with such success that the patients are freed from their former troubles and normally continent. The external meatus was intact and he inserted a trocar, passing through this and through the length of the superior urethral wall to the bladder, thus opening a passage through the inside of this thick muscular wall which answers perfectly for an urethra. He is watching the patients for any indication of contraction in the passage, ready to dilate the passages if necessary, as the conditions are similar to those following external urethrotomy in men, although so far no contraction has occurred in his cases.—*Presse Méd.*, November 6.

Gastrorrhagia Cured with Injections of Hot Water.—Prof. R. Tripier (*Semaine Méd.*, June 1) proclaims the surprising success of rectal injections of water at 48 to 50 degrees C., in arresting and permanently curing a number of threatening cases of gastric hemorrhage and black feces, which were about to be operated as a last resort. The patient reclines motionless and makes no effort to retain the water, which is injected at least three times a day. No food nor drink of any kind is allowed (except rectal, alimentary injections and artificial serum if thirst is excessive) for a week, when all trouble is usually at an end. He advises prompt application of this treatment at the first indications of gastrorrhagia, and suggests that it may prove effective in other hemorrhages by the reflex action of the hot water on the nerves of the intestines, which may possibly affect all sources of hemorrhage, internal or external.

Treatment of Herpes Zoster.—Dr. Leonard Weber (*Medical Record*) prefers locally at the onset, bismuth subgallat and talcum in equal parts, with sterilized gauze as a cover. When this is uncomfortable, subnitrate of bismuth, one part, to cold cream, three parts, may be spread on the lesions, to be continued until healing results. For the neuralgias after herpes he confides somewhat in ten to fifteen grain doses of quinin two or three times a day for a week. In a case of neuralgia after cervico-brachial herpes in an old man with sclerotic arteries, he gave for a month, with success, iodide of potash, grains x to xx, and strychnin, grains $\frac{1}{30}$, thrice daily. Aside from drug great quiet, in an even temperature, with good feeding and the essentials for restoration of normal bodily functions, are peremptorily demanded. The galvanic current may be a resort after quinin fails, but careful nursing, etc., constitute the really important adjuvants.

Simple and Effective Substitute for Hot Cataplasms.—With a continuous flow of hot water through a small flexible lead pipe, wound spirally around a joint, all the benefits of a hot poultice are secured with none of its disadvantages. The patient can attend to the simple process himself, with a couple of kitchen sauce pans and an alcohol lamp on a table beside him. The lead pipe communicates at each end with one of the paneby rubber tubing. The current is started by suction, when it continues indefinitely. A faucet in the outlet tube regulates the flow, allowing only a drop to escape at a time. The joint is held still and the heat regularly diffused by a shield made of three layers of plastered mull applied before winding the pipe around it. The same apparatus can be applied to the chest or abdomen, winding the tube in a flat coil over the plaster shield, or to the neck, etc. It has been well tested at Trendelenburg's clinic, with surprising success in gonorrheal and rheumatic joint affections, and seems to solve the problem of a simple, inexpensive, clean method of applying heat more or less permanently to any part of the body.—*M. Wilms, Deutsche Med. Woch.*, June 9.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
No. 61 Market Street (Occidental Bldgs.), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof-sheet returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, JULY 30, 1898.

THE MILITARY GOVERNOR OF SANTIAGO.

— *"En manos esta el pandero que le sabra bien taner."*

The Public Service column of the JOURNAL, May 7, 1898, page 1136, contains among other notices the following:

"Captain LEONARD WOOD, Asst. Surgeon, is relieved from duty in this city, Washington, D. C., and will proceed to the following named places in the order designated, for duty in connection with the recruitment of a regiment of mounted riflemen to be organized, under Section 7 of the Act of Congress approved April 23, 1898: Guthrie, Oklahoma Ter., Santa Fe, N. M., Phoenix, Arizona Ter., Carson City, Nev., Salt Lake City, Utah, Cheyenne, Wyo., Boise City, Idaho."

At that time who could have imagined what fate had in store for Assistant-Surgeon WOOD?

The rapid organization of the "Rough Riders": the election of Doctor WOOD as colonel; their success in being sent to the front with the first expedition; their bravery and gallantry in action; the epigrammatic advice of Colonel WOOD to his men in the trenches, "Don't swear! fight!"; the promotion of Colonel WOOD to be Brigadier-General, for gallantry on the field of battle—all these events have passed so quickly that it seems almost like a fairy tale.

General WOOD has now succeeded General McKIBBON as Military Governor of Santiago, and we feel sure that the choice of a medical man for this great and responsible position will result in great good to the country, the army, and the world—the country and the army by the enforcement of sanitary regulations while the troops remain in the vicinity of Santiago, and the world will be benefited by having eventually another healthy port in the tropics.

The sanitary officer can do little unless either clothed with ample power himself, or backed by those in

authority. General WOOD being invested with full authority, is now in a position where his sanitary training in the army will make him an ideal sanitary officer, and we fully expect to hear, in time, that Santiago, from being a danger point to the world's commerce, has advanced to the front rank as a salubrious spot.

No other man has ever had such a glorious opportunity, and General WOOD's record, although brief, is such as to give every assurance that this great sanitary work will be performed wisely and well. As the Spaniards say, "the drum is in the hands of one who knows well how to beat it."

NON-COMBATANTS.

When Assistant-Surgeon JOHN BLAIR GIBBS, of the United States Navy, was shot to death by the enemies of his country, to whose hostile fire he was exposed in the performance of his official duty, the word "non-combatant," by which he and others of his class have been almost sneeringly designated, ceased to have the pretense of propriety. When an assistant engineer yielded up his life in the engine-room of the *Maine*, along with the line officer who was likewise at his special station, the quibbler who would continue to dub the former only a staff non-combatant and the latter a military fighting man, would deserve ten-fold the contumely he would have imposed upon a brother soldier. When an assistant naval constructor performed the most heroic act in the existing war and won the admiration of soldiers of prowess all over the world, the bright light of his brilliant achievement brought into pitiable prominence the littleness which would deny him the right and title of a military officer.

It is not at all likely that these will be all the instances by which the staff officers of the Navy will vindicate their claim to be considered *bona fide* combatant officers, and though they have no Victoria Crosses displayed upon their breasts as on their British confères, to bespeak deeds of valor signally conspicuous where all men are valiant, the common sense of the American people and the justice of American legislators will surely recognize that tweedledee and tweedledum are miserable distinctions between men whose bodies are riddled by bullets on the self-same field of battle.

Bracketed between the names of Major ESKRIDGE of the Infantry and Second Lieutenant TURNER of the 6th, one reads among the wounded Dr. DANFORTH, Assistant-Surgeon, instead of First Lieutenant DANFORTH of the Medical Department, a careless oversight, showing how the old opinion of the medical officer as "nothing but a doctor" still lingers. Since in the army tardy but complete recognition of the military equivalence of the medical officer's status and function has been accorded, and when First Lieutenant DANFORTH of the Medical Corps of the army died from the wounds he had received from a Spanish sharp-

shooter while he was in the front in the very act of caring for other wounded, his real brothers in arms, who placed him in a soldier's grave, would be the last to say that he was only a non-combatant.

When WINTHROP CHANLER fell wounded at the attack on Las Tunas, Drs. LUND and ABBOTT carried him into the brush and all three sank up to their necks in the swamp. Dr. LUND, who was formerly a German army surgeon, and who is a giant in strength, managed to extricate himself, stripped off his clothing and swam in the darkness to find the ships. A boat from the *Florida* picked him up and he was taken over to the *Peoria*. As the strange figure clambered up the ladder, the sentry on guard at the gangway challenged him but Dr. LUND brushed past him and strode in his nakedness up to Lieutenant RYAN, gave the customary formal salute, and with the utmost gravity said, "I have come to report that the men over here require assistance." When CHANLER and Dr. ABBOTT were rescued they were still in the water up to their necks. Does it not savor of the ridiculous to call CHANLER a combatant and his heroic life-savers only non-combatants, merely because they were medical men?

The present war makes evident the difference between the military and naval services in this matter of the recognition of the military status of the so-called non-combatant staff. Among the roughest riders of Dr. LEONARD WOOD'S Rough Riders—he a Colonel and since a General, every inch of him, albeit a doctor—is Dr. CHURCH, a medical officer, one of Princeton's champion athletes, who wears a sword and carries a revolver, knowing well how to use both, and from the medical colonel down to the cowboy private, not one would intimate that he was only a non-combatant, when he checked his riding and dismounted to succor a wounded comrade of the troop. The shot that enters a man-of-war's boat at the bow, rakes the men pulling at the oars, and lands in the stern-sheets to maim or kill the lieutenant in command or the assistant-surgeon by his side, does its deadly work without regard to which is combatant or non-combatant; nevertheless antiquated tradition and ingrained custom concede to the dead as to the living medical officer only a relative (quasi or simulative) rank, instead of the same military status in the performance of an equally honorable, responsible and patriotic duty, involving precisely the same exposure to danger and the same risk of life.

The practical consequence of this difference in the status of the medical officers of the two services is pointedly illustrated in the instances of the hospital-ships, which the exigencies of the prevailing war have called into existence. The announcements that "yesterday the *Olivette* was made the military hospital-ship of the Fifth Army Corps and put under the command of Major A. H. APPEL of the Medical Department of the United States Army," and that "tomorrow the

U. S. Army Hospital-Ship *Relief* will sail under the command of Major GEORGE H. TORNEY, Surgeon United States Army," would occasion no remark or question in the Army, but in the Navy the assumed non-combatant character of the medical officer, however high his relative rank, precludes his discretionary control, charge, a technical command, and it is therefore considered essential that a line officer shall be on board as the authoritative superior dignitary. It would not be enough for the commanding medical officer, as in the army, to have a navigating officer under his command to perform the necessary nautical functions of going and coming, of anchoring and getting under way, of heaving to in a cyclone or edging off from a lee shore: naval tradition requires that there shall be a line officer, whether Admiral or Ensign, to exercise the prerogative of command, as well over Medical Director as over Acting Assistant-Surgeon. Hence the naval ambulance-ship *Solace*, although the creation of a medical officer and the embodiment of his ideas, is actually commanded by a line officer who directs these medical officers what they shall do or leave undone, nor has the Surgeon-General of the Navy the direction of its movements, as has his Army colleague of the vessels in the military service, which fly the Geneva Cross.

The *Navy Personnel* Bill, which failed to be enacted at the session of the Congress just adjourned, although indorsed and earnestly advocated by the Navy Department, after a remarkably able argument in its favor by former Assistant Secretary ROOSEVELT, proposed to do justice to one branch of the so-called non-combatant staff, by giving its officers actual (that is positive) rank, thus recognizing their equivalent military character; but the bill would have failed to do equal justice to the other staff departments—especially the medical corps—whose *bona fide* military importance has been already so often demonstrated during actual hostilities.

Hence, the medical officers of the Navy have very modestly and respectfully asked that they shall be put on precisely the same footing as medical officers of the Army of corresponding grades and length of service. As Colonel A. of the Medical Department of the United States Army is never by any possibility confounded with Colonel A. of the United States infantry or artillery, and as he never attempts to exercise a colonel's authority over a regiment or a battery or outside of his own department, it is claimed with equal reason that Commander B. of the Medical Corps of the United States Navy will never go on deck to supplant Commander B. of the line in getting up steam or coming to anchor, or in any other way exercise authority outside of the Ship's Hospital or over the men of the Hospital Corps. Just as Major C. of the Medical Department of the Army has had his rank and status defined beyond mistake or question, and his equivalence with all other Majors of Artillery,

Cavalry, Infantry, Engineers, Quartermasters, Commissaries, etc., determined, so does Lieutenant-Commander C. of the Medical Corps of the Navy, ask that he be legally declared to be entitled to all the rights, privileges and immunities of all other Lieutenant-Commanders, be they of the line, engineer, construction, pay or other corps, claiming that his intelligence, naval training and common sense would prevent him from attempting to violate the law by asserting or assuming an authority which his commission does not confer, and for which he would be certainly and properly punished by a court of his own colleagues, should he do so.

Our British cousins have satisfactorily demonstrated their right to military precedence. The London *Lancet* says: "When the medical history of the last war in India is written it will prove interesting reading. There were many difficulties overcome and hardships endured with the usual element of danger," and goes on to relate how, when the medical officers were at work extracting fragments of a missile from the leg of General WOODHOUSE, the Afridis crawled up and suddenly blazed into the hospital tent, sending thirteen shots through the canvas without disturbing the operation, "which went on as if there was no Afridi within a hundred miles." Surgeon-Captain BEYTS and Surgeon-Lieutenant HUGO have added their names to the already long list of medical military heroes in the British Army; and Lieutenant FORD, whose life was saved by the latter, after remaining over three hours with his unconscious wounded patient under a hot fire, will doubtless indignantly deny that a Surgeon-Lieutenant is not every bit the combatant hero that he was himself. The Victoria Cross pinned upon the breasts of such men loses nothing of its value as a distinctly military reward. Rather, the recital of the unparalleled deeds of bravery which have led to its bestowal in these instances, which lacked the maddening stimulus of the charge or the fierce excitement of an engagement, adds luster to the honored roll of its wearers. The percentage of medical officers who have won the Victoria Cross is already so great that its conferment upon another has ceased to be exceptional, and the corps to which these officers belong can no longer be denied an essentially military, therefore, combatant prestige.

What is in a name? A Lieutenant-General ought to be a less resounding title than Major-General, but it is not, and mere General, without any adjectival qualification, outranks all other kinds of Generals. It is the acquired significance of the title which has given each its importance, and military heroes are correspondingly exultant and flattered by their bestowal. Surgeon, however, has ceased to be even technically a proper designation for a medical officer either of the Army or Navy, and *Assistant-Surgeon* is an even more objectionable title for a subordinate who does not necessarily assist. So the attempted

professional designation of the Colonels and Lieutenant-Colonels of the Army Medical Department, as Assistant Surgeon-General and Deputy Surgeon-General has not been generally acceptable. Lieutenant-Colonel Jones of the Medical Department, U. S. A., Medical Director of the Department of the East; Major Brown of the Medical Department, Senior Medical Officer of the Fifth Army Corps; Captain Smith of the Medical Department, U. S. A., 14th Volunteer Infantry, are explicit and unmistakably distinct as would equally be Captain White of the Medical Corps, U. S. N., Medical Director U. S. Naval Hospital, Norfolk; Commander Green of the Medical Corps, U. S. N., Fleet Medical Officer, Atlantic Station; or Lieutenant-Commander Black of the Medical Corps, U. S. N., Senior Medical Officer U. S. S. *Hawaii*. With equivalent pay and privileges, the matter of line and staff contention would be forever settled, for there would be nothing left for which to contend. The *amour propre* of each department of the service would be satisfied and respected; the special functions of each would be defined; and the service become, as it should be, a brotherhood of men enlisted in the common cause of serving and defending their country.

And it may be pardonable here to state that a greater enemy than armed men and belching cannon is to be combated, and that by medical men alone—the enemy that lurks in the dark and strikes in the back, against whom earth-work and trench and rifle-pit are no protection, but into whose lair the medical officer walks undismayed, though knowing he may be the first of the forlorn hope to fall. No stricken soldier in the field will gainsay the title of *combatant* to the medical comrade who has saved him from death at the hands of this unseen foe.

MALINGERING.

In these enlightened times, when the great public knows well its rights, and knowing dares maintain, it is indeed rare for one of its members to receive an injury that he does not endeavor to make the party or parties whom he deems responsible for his suffering, compensate him for at least the losses he sustains during his forced retirement from his occupation. Such compensation is an act of justice, and in a majority of cases would be readily met by the company or individual responsible. But the injured man is rarely content with simple justice; his friends and his newspapers have warped his judgment and filled his mind with stories of large sums extorted from companies by men not nearly so severely injured as he imagines himself to be. Not infrequently a lawyer belonging to the "shyster" class arrives at his home before he has a chance of having his injuries properly dressed, and excites his cupidity by promising him a good sum in return for his injury, "and it will not cost you a cent contingent fee entirely. my

dear air." So suit is entered for many thousands of dollara, though happily the plaintiff is often after a few examinations ready to compromise for as many hundreds or less. At this point the most common of the various forms of malingering enters: an aggravation more or less marked of a symptomatology really present. He naturally thinks that the greater the amount of his apparent suffering, the greater the sum of money he will get, and the more readily the responsible party will be inclined to settle without suit. Your true malingerer usually disregards small surgical affections, fracturea, dislocations, sprains and the like, and strikes directly at the nervous system, for he seems to know instinctively the difficulty of diagnosing nervous diseases even among specialists. He then has a local paralysis or a "railway spine," about which he has read so much. The affection fixed upon may be feigned entirely, which is rare, or as mentioned above symptoms really present may be exaggerated. It must not be thought that this latter form is always feigned, and merely for purposes of gain. Surgeons who have attended a number of traumatic cases in which the injured parties have no chance of obtaining compensation, know well that neurasthenic symptoms not infrequently develop, and the victims have no idea but that they are seriously and permanently injured. It is astonishing what large numbers of such cases come to trial, and it is still more surprising with what readiness corporations will compromise even grossly unjust claims rather than submit to a suit, for well they know that the jury is prejudiced in favor of the injured party before a word of testimony has been offered. It is the poor man against the "grinding monopoly," and the average jury will side against the rich corporation every time, regardless of law or justice. Indeed, instances are on record where the judge was compelled to take the case out of the hands of the jury and award the fight to the defendant. That the medical profession is responsible in great part for this deplorable state of affairs cannot be denied and such things will continue until legislation decides the exact status of the so-called "medical expert." The term now is not only one of reproach but of ridicule as well: indeed, it could hardly be otherwise when the patent medicine charlatan, from the mere fact that he is the holder of a diploma, is able to meet the real scientist and deny the latter's statements with an equal chance of being credited.

There are forms of malingering where considerations other than those of a pecuniary nature are at stake, for this is a semblance of disease that involves classes, races and conditions of people, the sexes to an almost equal degree, and as regards age, from the cradle to the grave. The efforts of a child to escape punishment and the exaggerated complaints of the septuagenarian to excite sympathy and attention are familiar examples. Not common in this country,

where there is no compulsion to a military life, but of exceeding frequency abroad where some countries demand service training of all able-bodied males, all sorts of injuries and diseases are feigned to endeavor to evade the sharp eyes of the examining surgeon. Especially is this the case in times of actual fighting, when drafting of men become necessary to recruit the forces in the field; in times of peace, exaggeration of injuries or diseases said to have been inflicted or brought on when the claimant was a soldier. "*Said to have been*," for a history of the case may reveal the fact that the injury occurred years before enlistment. This "substitution of origin" (BAILEY), as it is called, plays a most important rôle in the science of malingering.

Probably the most successful of simulators are the poor and vagrant of our great cities, hospital habitués as they are sometimes called. The care and comfort, warmth and good food that the various hospitals and asylums afford, draw large numbers of these people of both sexes to their doors, and expert receiving physicians are often tricked by their artful representations. When in the wards their former experiences stand them in good stead in making themselves out as ill, with the result of obtaining comparative comfort for a few weeks, after which the experiment is tried elsewhere. Almost every physician of hospital experience will recall such cases which have been discharged after a few weeks with the diagnosis of "malingerer." The ailments they will counterfeit embrace the entire range of the science from medicine to the specialties. Their particular trouble largely depends on the particular ward they have occupied during a former stay. Indeed it is not too much to say that they study the symptoms of their immediate neighbors with as lively an interest as the attending physician. Neuralgia and rheumatism, headache, epilepsy, insanity and coma are especial favorites. The obstetrician not infrequently finds cases of phantom tumor. The surgeon encounters cases of simulated tumors and strictures, while simulated blindness and deafness are by no means rare finds for the specialist in those fields. One of the most common attempts in recent days to extract money from a recalcitrant corporation is the attempt to palm off an old hernia as being the result of some recent injury. Some most flagrant attempts of this character have recently fallen under our personal observation.

THE DANGERS OF TINNED FOODS.

From time to time we read in the daily press accounts of poisoning by food products, more particularly by those that are prepared in large quantities and sold in tins or canned packages. Perhaps it is just as frequent, if indeed not more so, for investigation to reveal that the really poisonous effects are due to carelessness in the preparation or in some

defect of the cooking utensils and that there were no canned goods used whatever. But this fact does not do away with a certain prejudice or fear that impels the public to attribute, on the first impulse, all these accidents to the use of these products, though not apparently with the result of very greatly reducing their consumption. Ptomaines, we are aware, may be generated in fresh as well as in preserved meats, and acid can corrode cooking utensils as well as preserving tins, but it is more natural to assume that time and defective preparation in the wholesale establishments are at fault than that the sufferers themselves were in any way responsible. The cheapness and convenience of the canned goods, however, keep them in popular favor, and the temporary loss of confidence in their wholesomeness seems on the whole to have little effect on their sales. It is estimated that in Great Britain alone their consumption amounts to 581,000 pounds daily; a figure that indicates the extent of their demand when one bears in mind that it can be, at best, but a small fraction of the total consumption.

There are, nevertheless, some special dangers in canned foods if they are carelessly or fraudulently prepared, and these have been very well discussed by Dr. BROWN, an English local health officer, in a paper in the *Journal of the Sanitary Institute* for April of this year. The dangers of canned meats are from ptomaines, and these may be developed before canning, after canning, and more than at any other time after opening. The first contingency is probably a rare one, though it is possible that unwholesome meats may be put up and the methods of preparation be insufficient to counteract the growth of ptomaines. In cases of putrefactive changes after canning, the bulging tin is generally a sufficient indication, but there is no security against bacteria after the package has been opened and the contents not immediately disposed of. The age of the contents, other things being equal, is no bar to their wholesomeness; Dr. Brown has tested packages twenty and thirty years old, and except a slight loss of freshness of flavor found them still serviceable.

Canned fruits, on the other hand, are more liable to deteriorate with age; and the dangers in their case are chiefly the absorption of mineral poisons from their receptacles. This goes on at a steadily increasing ratio each year, and freshness is therefore a prime requisite for their perfect wholesomeness. It is probable that many acid canned fruits contain appreciable if not really dangerous quantities of malate of tin and other salts. The quality of the tin and solder used is an important element in the case; Dr. Brown holds that over 1 per cent. of lead in the tin or over 10 per cent. in the solder should be considered dangerous. In some cases considerable solder escapes into the can from careless soldering, and this is also objectionable. It would be in all respects better if fruit could be put up exclusively in bottles or jars

without even metal tops, as regards the question of safety to their consumers.

The cautions Dr. BROWN suggests may be repeated here. They are: Use soon after opening; keep the cans in a cool place, as heat favors fermentation; examine plating of interior of can and distrust corrosion or any bluish slate color as risky; avoid resold-ered goods; and do not take the cheapest, as they are likely to be the worst. A valuable reform which he recommends would be to have the date of canning stamped on every package, and this is the most important for canned vegetables and fruits. This is, it is said, compulsory by law in Germany, and it would be well were it so for the home market also.

In spite of all the possibilities of evil, the rarity of trouble from the use of canned goods speaks well for the general honesty of the manufacturers. It is well that it is so since, were it otherwise, a cheap and palatable class of foods would have to be distrusted and often, in common prudence, disused.

WAR NEWS OF THE WEEK.

The war news of the week has not been of an exciting character, although it concerns the progress of an outbreak of yellow fever in an army of twenty thousand susceptible men exposed to the infection, under conditions of fatigue and exposure which would be expected to measurably increase their susceptibility. The first cases of yellow fever appeared July 7, when four cases were taken from a house occupied by our troops at the front. A fifth case was discovered next day in a house in Siboney, directly across the road from the fever hospital established by Dr. GUITÉRAS. The danger of occupying such houses was strongly set forth and widely distributed in a circular from the office of the Chief Surgeon; but this advice was disregarded. The houses, filthy beyond measure, were crowded with soldiers and utilized as offices and store-houses. Shortly after this they were all destroyed by fire under the orders of the commanding general. While Colonel GREENLEAF, chief surgeon on the staff of General MILES, remained at Siboney he telegraphed daily the progress of the disease, but since his embarkation for Porto Rico the information received from the vicinity of Santiago has been meager. The latest information, under date July 23, is to the effect that there are about fifteen hundred patients in the hospitals but that only one hundred and fifty of these are yellow fever cases. Meanwhile the troops have been moved to better camping grounds where a fine breeze usually blows from 9 A.M. until sunset. The atmospheric humidity at the present time is very great, a constant steam or mist rising from the ground. Heavy clouds hang over the hills most of the time, and on the lower grounds early in the day. Rain falls only in the afternoon or night, three or four times a week, and although the showers last but a short time they are so heavy that the poncho and shelter-tent

give little protection. The ground is so porous and its surface configuration so irregular that the heavy rainfall is either absorbed or drained off in a short time.

Such are the conditions before the army medical officers of the Fifth Army Corps at the present time. Whether they will be able to control the disease by prompt isolation of yellow fever cases, and the removal of regiments from infected localities remains to be seen. Up to the time of the surrender they were handicapped by the military necessity which required the troops to occupy certain lines, irrespective of yellow fever infection, and during that time the slow progress made by the disease shows the influence of their restrictive measures. It is to be hoped that they will be able, under the better conditions now existing, to embark the regiments for the United States with a clean bill of health, while the immune volunteers take their place as the garrison of Santiago.

WOUNDS AND DISEASE AT THE FRONT.

Medical officers returned from Cuba with sick and wounded from General SHAFTER'S command have given us interesting details of the medical and surgical work during and after the engagements at Santiago. On the debarkation of troops at Baiquiri they were pushed rapidly forward, each man carrying his blanket roll and three days' rations. Regimental surgeons with their hospital corps men accompanied their respective commands; but all regimental medical and surgical chests, dressings, etc., were of necessity left behind, as no horses or mules had as yet been landed. Surgeons applied to higher authority for their medical property and sent back to Baiquiri to endeavor to recover it; but in the meantime the vessels, emptied of troops, had been ordered out of the harbor and had gone to ports unknown or lay too far out at sea, with no way of communicating with them. Ultimately a launch was procured and some of the regimental medical supplies were gathered up from such of the transports as could be reached. Thus, although the army had embarked with adequate first aid supplies, only a percentage of them was available when the time came for their use. Fortunately, however, the men carried the necessary dressings on their persons, for every soldier of the army, with the exception of the men of one regiment, was provided with the official first aid dressing packet containing two antiseptic compresses of sublimated gauze in oiled paper, one antiseptic bandage of sublimated cambric with a safety pin and one triangular bandage, also with a safety pin. Fortunately also, the arrival of the ambulances from Tampa and of the *Relief*, the hospital ship despatched by the Surgeon-General to meet just such an emergency, put an end to what would otherwise have been a difficult situation.

According to Captain E. L. MUNSON, who was one of the operators at the field hospital, surgical opera-

tions were required only in shell wounds. Wounds by the Mauser bullet were apparently either immediately fatal on the field or trivial in their subsequent course. There were no explosive effects from the brass jacketed bullet of the Mauser rifle, the wound of exit in most instances being scarcely larger than that of entrance. Long bones were usually perforated, without comminution, often even without fracture. Only about thirty-five cases required splints. Abdominal wounds were classed among the immediately fatal, as few of them were seen in the hospital. There was little hemorrhage. The Mauser bullet deformed frequently, but even then it did not make the ghastly wounds that were expected. Keyhole wounds made by the bullet when striking with its long axis were fairly common. Many bullets, even when fired at short range, lodged instead of perforating. In eight out of forty-one consecutive cases the bullet was lodged. This was attributed to an inferior or a deteriorated character of the powder in the cartridges supplied to the Spanish infantry. Antiseptic first aid was eminently successful, wounds healing quickly under a scab.

Malarial fevers were infrequent at first but after the rains began to fall they became quite prevalent. A number of cases of typhoid fever and measles occurred, due to infection brought with the troops from the United States. Heat exhaustion and a mild type of sunstroke incapacitated a number of men from duty. Diarrheas and dysentery are rare, a fact attributed to the purity of the water supply. Baiquiri is supplied by a pipe-line from the river of the same name, a pure, limpid stream flowing rapidly over a pebbly bed. The water at Siboney comes from the pipes of the Juragua Iron Company, which run to their wharves near the city of Santiago, following the tracks of the company's railroad for about twelve miles. The hospital is pitched close to this pipe at Siboney and has thus an easily available and unlimited supply of pure water; while at the front the troops obtained water from springs and from the Aguadores, a branch of the San Juan river. Yellow fever is of course the disease in which is centered the interest of the medical officers at the front.

CORRESPONDENCE.

Treatment of Tetanus.

AUSTIN, TEXAS, July 20, 1898.

To the Editor:—I send you report of a case of tetanus treated successfully by the use of antitetanic serum. The diagnosis of the case I believe to have been correct, as shown by the history, the symptoms, the response to each dose of the serum, and, further, that the patient lived ten miles in the country, and was not familiar with the symptoms of tetanus.

A study of this case shows the immediate response to the antitetanic treatment, *i. e.*, the pulse, temperature, pain, stiffness and restlessness were all reduced soon after the injection was given. It can further be seen that the dose of serum should have been repeated sooner in this case; but owing to

the inaccessibility of the patient it could not be done. There were no unfavorable effects from the use of the serum, not even an eruption.

I give the case in detail, as follows: On June 14, I was called to see a case of tetanus, in consultation with Dr. F. A. Maxwell, near Austin, Texas. Minnie T., age 19 years, weight 180 pounds, of robust constitution, on June 6 was in the cow and horse lot and stepped on a rusty nail which entered the fleshy part of the foot for some distance; the nail was removed, there was but little bleeding, turpentin was applied externally and no more notice taken of the foot other than that caused by the attendant soreness usual in such cases, until the afternoon of June 13, when she noticed sharp pains in the wound, running up the leg, especially noticeable when pressure was made over the seat of injury; also pains extending up the spinal column, especially the neck, with a decided stiffness of the jaws and a twitching of the muscles of the arms and legs at times and much nervousness and excitability. Dr. Maxwell had examined the foot, found it tender in the neighborhood of the wound, which had healed, and he made an opening and washed it out with carbolic acid solution and ordered it poulticed to relieve the pain; gave doses of calomel to move the bowels and left potassium bromid to be given every few hours as indicated. The next day I was called in consultation with Dr. Maxwell and found the patient with a pulse of 108, temperature 99.5 degrees, very restless; the pains seemed to run from the foot up the leg and extend on up the spine; there was much stiffness of the jaws; she could, with much difficulty, open the teeth as much as half an inch; peculiar sensations, as she described them, would run up her back and the slightest breeze was sufficient to bring them on. Dr. Maxwell and I decided to administer antitetanic serum at once. We thereupon, at 4 P. M., June 14, injected subcutaneously, in the right gluteal region, one-third of a ten c.c. bottle of fresh liquid antitetanic serum (Parke, Davis & Co.), using the regular antitoxin syringe and observing all antiseptic precautions. The patient was seen again at 10 P. M. She had slept from 6 to 9:30, felt well, pulse 90, temperature normal, stiffness greatly reduced in jaws and slight perspiration.

June 15—Seen at 10:30 A. M., pulse 73, temperature normal, no pain; but tenderness in the muscles of the foot, a little stiffness in the jaws; had rested well the night before until 5 A. M.; she was then given potassium bromid and slept quietly until morning.

June 16—Seen in the forenoon, she was a little restless, slept well the night before, condition as on former day, except pulse more frequent (90), temperature normal; at 6 P. M. was more restless, complained of the jaws, soreness in the limbs, pain in the stomach, temperature 99, pulse 96; the second dose of the serum was given, also potassium bromid and chloral hydrate.

June 17—Patient slept well the night before, all the symptoms had improved and the pulse and temperature were normal.
